The Honorable Scott Pruitt
Secretary
Environmental Protection Agency
1200 Pennsylvania Ave, N.W.
Washington, DC 20460

Dear Administrator Pruitt:

I write to request a 90 day extension to the public comment period regarding EPA's second five year review of the Hudson River PCBs Superfund Site. The report is more than 1000 pages, and includes detailed technical data and assessments. Its findings have ramifications for stakeholders along a 200-mile stretch of the Hudson River from Hudson Falls, New York to New York City. Therefore, I do not believe that EPA's 30 day comment period is sufficient. It is vital that local residents, community and environmental organizations, business leaders, state and federal agencies, as well as the Hudson River Natural Resource Trustees, and representatives from the Community Advisory Group have the opportunity to review and evaluate the results and make their voices heard.

The five year review presents an opportunity to realize goals that you have articulated, including the importance of cleaning up the Hudson River pollution, ensuring the Superfund program succeeds in achieving both environmental outcomes and creating jobs. When EPA announced the Hudson River cleanup 15 years ago, it was a promise to New Yorkers that the long-damaged river would finally be on the path to a rapid recovery. However, after the cleanup plan was established, EPA discovered that at least 2-3 times more PCB contamination existed in Hudson River sediments than had been assumed; yet EPA did not modify the scope of the cleanup. As a result, the Hudson River remains contaminated at levels far beyond the cleanup targets EPA established. Economic development on the Upper Hudson River has long been stifled by the dark cloud of toxic pollution; communities cannot wait decades longer for a clean and usable river. Long-term "natural attenuation" of PCBs is not a solution to this problem. The PCBs in the Upper Hudson River are continuing to be transported down-river as far as New York Harbor and beyond. PCB levels in fish in the lower Hudson River are not declining as expected, pointing to the need for investigation of downriver contamination and appropriate remedial action.

New York State has a long and proud history of environmental protection in conjunction with economic development, and the Hudson River is a national symbol as an American Heritage River. New Yorkers live, work and play along the Hudson River. I strongly believe that additional cleanup is needed. A credible five year review is crucial to ensure the integrity of the federal Superfund program, given that the Hudson is one of the largest and most visible sites in the country.

It is essential that those who are most directly impacted have a sufficient opportunity to review and respond to the EPA report. I urge you to extend the public comment period for this important purpose.

Sincerely,

Kirsten Gillibrand

Kirsten Gillibrand

United States Senate
WASHINGTON, DC 20510

July 18, 2017

Administrator Scott Pruitt
Environmental Protection Agency
1200 Pennsylvania Avenue, NW
Washington, DC 20460

Dear Administrator Pruitt:

We write to urge the Environmental Protection Agency (EPA) to hold a public information meeting in New York City regarding the Proposed Second Five-Year Review Report for the Hudson River Superfund Site. It is crucial that the local community, including those along the Lower Hudson River, have the opportunity to hear directly from the EPA on this proposed report and to have their own voices be heard.

We appreciate that the EPA has already held a public information meeting in Poughkeepsie, and has another meeting planned in Saratoga Springs on July 19. However, we believe it is important that the EPA hold an additional meeting in New York City, as well, to give the maximum number of New Yorkers who live adjacent to the Hudson River an opportunity to participate in the public comment process. There is a significant population of residents in New York City who may have an interest in the status of the cleanup of the Hudson River PCBs Superfund Site and they should have maximum ability to learn about the status of this endeavor and to offer their views on current and future plans in this regard. With Poughkeepsie located more than 80 miles away from New York City, and Saratoga Springs more than 180 miles away, EPA should do more to ensure that potentially interested communities have the opportunity to hear directly from the agency and participate in the public comment process, particularly since some elderly, disabled, low-income, and other residents who have hectic schedules, yet who wish to engage in the process, may have a difficult time attending a meeting so far from home. It is for this reason that we urge the EPA to hold a public information meeting in New York City on this Proposed Second Five-Year Review Report as soon as possible.

Thank you in advance for your consideration of this request. Should you have any additional questions, please do not hesitate to contact our offices.

Sincerely,

Charles E. Schumer
United States Senator

Kirsten Gillibrand
United States Senator

Public Comment for Submission: Hudson River PCBs Superfund Site Second Five-Year Review

Re: Hudson River PCBs Superfund Site Second Five-Year Review

Dear Director Klawinski,

On behalf of the people of the 106th Assembly District of New York, and as a resident of the beautiful Hudson River Valley, I write to urge the EPA to continue active remediation efforts in the Upper Hudson as well to investigate PCBs in the Mid and Lower Hudson. The Hudson River, often called America's River, is a vital economic, recreational, and cultural resource for millions of people. It is the historic spine of our region and a critical source of water for communities and businesses on its shores. The EPA must do more to ensure the remediation will protect human health and the environment, and meet the goals from its original Record of Decision (ROD) in 2002.

Analysis from National Oceanic and the Atmospheric Administration (NOAA) and the US Fish and Wildlife Service (USFWS) suggests pre-remedial PCB concentrations in areas targeted for dredging were 2 to 3 times higher than EPA anticipated. Higher than anticipated levels of surface sediment contamination was found in portions of River Sections 2 & 3, areas not designated for dredging. Data also suggests the lower 150 miles of the river is not responding to the dredging as anticipated, and PCB concentrations in fish have not declined. According to the EPA's own analysis, it will be, at minimum, over 50 years before New Yorkers can safely eat one half-pound fish meal from the Hudson River once a week without negative health effects. Our communities should not have to wait generations to safely eat locally caught fish.

General Electric fought for decades and spent millions to avoid cleaning the over 1.3 million pounds of PCBs it dumped into the Hudson River. We are asking the EPA to stand up for the people that live by, work on, and visit the majestic Hudson River, and tell GE to take responsibility for the tremendous damage it has done to the river and the local economy. The

EPA must require GE to achieve “protective” status for the entire 200-mile stretch of the Hudson River ensuring that PCB levels are truly safe for humans and the environment.

I hope the EPA will consider the people of New York when makings its decision about our River’s vitality.

Sincerely,

Didi Barrett
Assemblymember, 106th District

RE: Hudson River PCB Dredging Five Year Review

Dear Director Klawinski,

I have the privilege of representing the beautiful 106th Assembly District, which includes twenty municipalities in Columbia and Dutchess Counties; seven of these are riverfront communities.

The Hudson River is the lifeline of this region: It connects us economically, culturally, and historically. I believe the EPA's decision to discontinue the dredging of PCBs is premature and will leave the region with a contaminated river for decades to come. The fact is the river is still contaminated. Data presented by the National Oceanic and Atmospheric Administration, the New York State Department of Health and the New York State Environmental Protection Agency all say the river is not yet safe for the health of humans, wildlife and the environment.

The Hudson River Valley is home to a stunning array of natural treasures, a robust tourism industry, countless historic landmarks, the landscapes of America's first artistic movement and thousands of residents and businesses that depend upon the iconic Hudson, America's River. A safe and healthy river is within our reach. I urge you not to stop only part way to that goal. Please keep dredging the river until all of the PCBs are removed.

Thank you for your consideration. Please feel free to reach out to my office if you have any questions or concerns.

Sincerely,

Didi Barrett

Mr. Gary Klawinski, Project Director, EPA
US EPA Hudson River Field Office, Region 2, 187 Wolf Road, Suite 303
Albany, NY 12205

Dear Mr. Klawinski, Project Director, EPA,

September 1, 2017

Administrator E. Scott 'Scott' Pruitt
Mr. Gary Klawinski, Project Director, EPA

RE: U.S. Environmental Protection Agency's (EPA's) Proposed Second Five-Year Review Report for the Hudson River PCBs Superfund Site.

Dear Administrator Pruitt and Mr. Klawinski:

As a member of the New York State Assembly and both the Assembly Environmental Conservation and Health Committees, I am writing on behalf of the residents of Rockland County, NY, my constituents in the 97th Assembly District, and the communities I represent, including the Hudson River Villages of Nyack, South Nyack, Piermont, Grandview-on-Hudson, Upper Grandview, and the Hamlet of Palisades, to express my serious concerns regarding the U.S. Environmental Protection Agency's (EPA's) Proposed Second Five-Year Review Report for the Hudson River PCBs Superfund Site.

The Hudson River is a critical resource vital to the quality of life in our communities. The PCB cleanup is not performing as planned and thus the remedy is neither protective of human health nor the environment. Consequently, I strongly urge you to order further dredging in the Upper Hudson River, and to order a full remedial investigation and feasibility study in the Lower Hudson River as soon as possible.

EPA's review must clearly state "the remedy is not protective." In the report you admit that General Electric's (GE's) cleanup of toxic PCBs it dumped into the Hudson River does not currently protect the health of the public or the river. That should be the only finding of the report. And you must remove the phrase "the remedy will be protective." Such a statement conflicts with your agency's admissions that the cleanup is not protective now, that at least eight more years of data are needed to predict future trends with any confidence, that the short-term five-year fish tissue goal will not be met, and that more investigation is needed in the

lower 150 miles of the Hudson River.

The economic, recreational, cultural and scenic value of the Hudson River form the bedrock of past development as well as the future vitality of the Hudson Valley and New York City. General Electric's negligent dumping of more than a million pounds of toxic PCBs into the Hudson River for more than 30 years resulted in a once vibrant commercial fishing industry being shut down. Today, the Hudson River is one of the nation's largest Superfund sites, and the consumption of fish from the River has been significantly restricted. As demonstrated by the public outcry at EPA's information meetings on its Five-Year Review Report, and at a time when many of our communities have long-term waterfront revitalization goals that will increase tourism, create jobs, and boost our local economies, New Yorkers want a healthy Hudson River as soon as possible.

The goals set forth by EPA to clean up the Hudson River are already weak. In the Upper Hudson River--the 40 miles north of the Federal Dam in Troy, NY--EPA expected that within five years of the completion of dredging, it would only be safe to eat one fish meal every two months, and that within 16 years, it would only be safe to eat one fish meal per month. Under the cleanup plan, EPA did not expect people to be able to eat one fish meal per week for over 55 years. Because the timelines for the cleanup are so long, I expect EPA to hold GE accountable for meeting not moving the goal posts. In the meantime, I am concerned about the many people who eat fish from the Hudson River, and I urge EPA to do better outreach to subsistence and recreational fishing communities about the health risks involved in doing so.

EPA's determination that the cleanup "will be protective" of human health and the environment of the Upper Hudson River is unacceptable. This determination is inconsistent with the agency's admission that the cleanup is currently not protective and with EPA's repeated statements that at least eight more years of data are needed to predict future trends with any confidence.

EPA's determination is further undercut by the agency's reluctance to provide specific timeframes for reaching the short- and long-term goals. In addition, the National Oceanic and Atmospheric Administration (NOAA) recently published a peer-reviewed study suggesting that hazardous levels of PCBs will remain in fish in the Lower Hudson River for much longer than the EPA predicts. The New York State Department of Environmental Conservation (NYSDEC) has also expressed its concerns with the findings in the report, stating that the significant amount of contamination left in the river threatens both public health and the environment. Therefore, EPA should revise its determination and recognize that the cleanup is not protective of human health and the environment.

The data show that the Lower Hudson River--the 150 miles south of the Federal Dam--is not responding as anticipated. EPA essentially admits that the cleanup is not working in the Lower Hudson River by failing to make a protectiveness determination that covers this stretch. From Poughkeepsie and continuing downstream, the decay rates (or rate of decrease in PCB concentration) in fish are not statistically different from zero. NYSDEC and the Hudson River Foundation do not expect the dredging to result in additional improvement in the Lower Hudson River.

While EPA agrees that more investigation is needed, the agency has made no definite plans on how this will be done. Therefore, I urge EPA to require GE to do a full remedial investigation and feasibility study of the Lower Hudson River.

EPA should be transparent regarding the facts in its Five-Year Review Report. For instance, during Phase 1 of dredging, EPA discovered that it had underestimated both the depth of the PCB contamination and the concentration of PCBs in the surface sediment. Despite acknowledging that there were more PCBs present, EPA did not change the goals for the cleanup. Instead, EPA focused on removing a certain percentage of contaminated sediment, leaving behind two to three times more PCBs than anticipated. NOAA has stated that this means that cleanup goal targets will be met up to 60 years later than expected. The public has a right to know how much PCB contamination remains in the Hudson River today, and I urge EPA to make that information clear and accessible in its final report.

In short, for the Upper Hudson River, EPA has failed to evaluate all of the signs that the cleanup will not meet its goals, and instead has made a determination that is not grounded in science. For the Lower Hudson River, EPA has recognized that the cleanup is not working as anticipated, but it has failed to provide a plan for a prompt investigation and cleanup. If Administrator Pruitt's words about implementing Superfund better and faster mean anything at all, they should cause EPA to make a "not protective" finding for the entire Hudson River Superfund Site, order GE to take more PCBs out of the Upper Hudson River, and compel GE to devise a real cleanup of the Lower Hudson River.

Respectfully submitted,

Ellen C. Jaffee
Member of Assembly,
97 (AD)

Sincerely,

Ms. Ellen Jaffee

Subject: Letter Re Hudson River PCBs Superfund Site

Hey Larisa,

In response to the release of Hudson River Superfund site: Second Five Year Review Report, Senator Carlucci would like to submit the attached letter to the EPA signed by other senators whose districts border the Lower Region of the Hudson River Superfund site.

Oscar Dunham
Director of Operations
The Office of New York State Senator David Carlucci (SD-38)
(Rockland Office) 845-623-3627
(Albany Office) 518-455-2991

THE SENATE
STATE OF NEW YORK
ALBANY, NY 12247

August 28, 2017

The Honorable Scott Pruitt, Administrator
U.S. Environmental Protection Agency
Ariel Rios Building
1200 Pennsylvania Avenue NW
Washington, DC 20460

Re: Hudson River PCBs Superfund Site Second Five-Year Review Report

Dear Administrator Pruitt,

As members of the New York State Senate delegation whose districts border the shoreline of the Hudson River PCBs Superfund site, we are writing you today to express our concerns over the findings stated in the U.S. Environmental Protection Agency's (EPA) Hudson River Superfund site: Second Five Year Review report released on June 1, 2017.

The Hudson River, specifically the Lower Region, is home to millions of New Yorkers who reside along the shoreline and is a keystone of the Hudson Valley's $5.2-billion tourism economy responsible for more than tens of thousands of jobs in the region as well. Moreover, plans for future economic development along the Hudson River and its shoreline have been developed by state and local agencies – including the renewal of the once vibrant commercial fishing industry.

While the Second Five Year Review report does acknowledge the need for more investigation in the Lower Hudson River, the conclusion of the report clearly ignores the failure of the cleanup to meet health and ecological targets established by the EPA when it selected the dredging project for the Upper Hudson River. The report states that PCB levels in the Lower Hudson River, between the Troy Dam and the tip of Manhattan, have not demonstrated expected declines resulting from Upper Hudson River dredging. Consequently, it is abundantly clear this Superfund project has not gone far enough – empirical evidence demonstrates this.

Furthermore, two other federal agencies, the National Oceanic and Atmospheric Administration (NOAA) and the U.S. Fish and Wildlife Service (USFWS), recently published a peer-reviewed study suggesting hazardous levels of PCBs will remain in fish in the Lower Hudson River for much longer than the EPA predicts. The New York State Department of Environmental Conservation (NYSDEC) has expressed their concerns with the findings in the report, stating that significant amount of contamination left in the river threatens both the public health and the environment. Even more disconcerting, other EPA officials have confirmed that not until fifty-three years from now, people would be able to eat a fish-meal from the Hudson River without facing serious health concerns.

Without the EPA taking additional remediation steps in the Lower Hudson River, restoring the health and well-being of people subsisting on the river's polluted fish and developing job-creating riverfront revitalization projects will be suspended well into the 22nd century. If the EPA fails to take action, New York taxpayers will be forced to foot the bill to clean up a mess they did not create. Neither option is acceptable.

Therefore, we respectfully request for EPA to direct General Electric (GE) to develop an adequate plan of action for the additional removal of PCB-contaminated sediment in the Lower Hudson River to meet human health and ecological satisfactory levels in a timely manner. Additionally, we further request for EPA, in coordination with other agencies, to provide more effective outreach regarding fish consumption advisories along the Lower Hudson River shoreline.

Thank you in advance for your time and attention to this matter.

Sincerely,

Senator David Carlucci

Comments to EPA on Second Five Year Review on Hudson River PCB Cleanup.pdf;

Hello,

Attached are comments on the EPA's Second Five-Year Review Report for the Hudson River PCBs Superfund site from New York State Senators Brad Hoylman and Daniel Squadron. A hard copy was also submitted at last night's public hearing at John Jay College.

Thank you.

Re: Comments on EPA's Proposed Second Five-Year Review Report for the Hudson River PCBs Superfund Site

Dear Director Klawinski:

Thank you for the opportunity to submit comments on the Environmental Protection Agency's (EPA) Proposed Second Five-Year Review Report for the Hudson River PCBs Superfund site. As representatives of Senate Districts that abut the Hudson River in Manhattan, we write to express our deep concerns that the preliminary review does not recommend more cleanup of the river. We urge the EPA to revisit the terms of its 2005 settlement agreement with General Electric (GE) in light of widespread evidence that calls into question the efficacy of the agreement's remedy.

For more than three decades, General Electric knowingly dumped millions of pounds of toxic polychlorinated biphenyls, or PCBs, into the Hudson River. As a direct result of PCB contamination – which has been linked to cancer, low birth weight, thyroid disease, and learning, memory, and immune system disorders – the EPA classified parts of the Hudson as a Superfund site and mandated that GE remediate the river through dredging. After GE ostensibly met the terms of the settlement agreement, EPA allowed the company to begin dismantling its dredging equipment in November 2015. However, subsequent reports indicate that GE removed only 65% to 72% of PCBs.[1]

Unfortunately, the Hudson River is far from remediated, and recent studies suggest the extent of the damage may be worse than originally thought. The three trustees of the Hudson River – including the National Oceanic and Atmospheric Administration (NOAA), the U.S. Fish and Wildlife Service (FWS), and the New York State Department of Environmental Conservation (DEC) – as well as numerous environmental watchdog organizations and even the EPA's own analysis have all found evidence that the cleanup is not complete.

[1] Nearing, Brian, "EPA says Hudson PCB cleanup shows improvement, more study still needed." Times Union, June 1, 2017: http://www.timesunion.com/allwcm/article/EPA-says-Hudson-PCB-cleanup-shows-improvement-11188727.php

In November 2015, FWS and NOAA released a statement on the Hudson River Demobilization Plan to dismantle dredging equipment, stating: "Although the dredging has removed some of the contamination, it has not addressed nor compensated the public for injuries to natural resources. Trustees have determined that GE's PCBs have injured groundwater, fish, waterfowl, surface water, and navigational services of the Hudson River for decades, and these injuries will continue well into the future."[2]

In May of 2015, NOAA issued a report[3] examining the model projections used as the basis of the 2005 agreement between EPA and GE, finding that the "original models used were overly optimistic" and overestimated the rate of natural recovery in the Hudson River. As a result, achieving the EPA's remedial objectives "will take longer than predicted." Ultimately, NOAA concluded, "[a]dditional removal of PCB-contaminated sediment in the Upper Hudson River [is] needed to achieve [the] reductions in Lower Hudson River fish PCBs" that were initially anticipated by the EPA.

The same report found that the amount of PCBs remaining in the Upper Hudson River after GE leaves is likely to be three to five times higher than EPA initially forecast, and the rate of recovery of the river is expected to take generations longer than predicted — an additional 40 to 50 years. In other words, because of the flawed modeling used by the EPA over a decade ago, if GE's federally-mandated dredging is allowed to conclude the EPA will have fallen far short in achieving its intended remediation.

As the state agency that serves as a trustee to New York's Hudson River, DEC is uniquely positioned to understand the local impact and effectiveness of the cleanup. In December 2016, DEC released an independent review of PCB contamination in the Hudson River, informed by EPA guidelines and criteria, and shared its findings with the EPA. DEC's recommendations found that "despite the substantial remedial work done in constructing the dredging remedy between 2009 and 2015, the risks to human health and the environment are well above the EPA acceptable risk range, and … unacceptable exposures are still occurring." The report recommended the EPA conduct additional studies on the effectiveness of the remedy, update its data and scope to optimize the remedy, and expand its site investigation to the Lower Hudson between the Federal Dam at Troy and the Battery in Manhattan.[4]

The EPA itself has said it will take 55 years before it is safe to eat Hudson River fish once per week.[5] While certainly the remedy will not be immediate, this time frame is

[4] DEC report: http://www.dec.ny.gov/docs/fish_marine_pdf/hudsondredging5yr.pdf
[5] Hill, Michael, "Q&A: Controversy lingers after $1.7B cleanup of Hudson River." AP, June 27, 2017. http://poststar.com/news/state-and-regional/q-a-controversy-lingers-after-b-cleanup-of-hudson-river/article_548495e4-73d5-597f-ba3e-2efdccfb223c.html

concerning, especially because the EPA's Second Five-Year Review Fact Sheet from June 2017 states, "The EPA's five-year review acknowledges that more years of post-dredging data are needed to identify, with a higher degree of confidence, long-term trends in the river's recovery."[6] The lack of clear data about trends impacting the river's long-term recovery, paired with warnings being raised from the river's trustees, should be sufficient justification to revisit the terms of the settlement agreement.

Environmental advocacy organizations, including Riverkeeper, Scenic Hudson, NRDC, Sierra Club Atlantic Chapter, Hudson River Sloop Clearwater and many others have highlighted these widespread expert opinions on the cleanup and concur that more work needs to be done.

On the basis of the foregoing, we once again strongly urge the EPA to revisit the terms of the 2005 agreement to ensure that GE completes a thorough and effective cleanup of Hudson River PCBs.

Sincerely,

Re: Hudson River PCBs Superfund Site Second Five-Year Review

Dear Director Klawinski,

We write to you as the elected representatives of millions of New Yorkers living along the banks of the Hudson River and beyond. Our constituents look to the Hudson as a vital economic, recreational, and cultural resource, part of the heritage of all New Yorkers and all Americans. As stewards of that heritage, we urge you to revise the second Five-Year Review of the Hudson River PCBs Superfund Site to declare that cleanup efforts completed thus far are **not protective of human health and additional remediation and evaluation is required** to restore the river and meet the goals set out in the Record of Decision.

Although dredging of PCB-laced sediment in the Upper Hudson was effective at removing PCBs from the riverbed, data has shown that two to three times as many PCBs remain in the river as expected. Additionally, PCB levels in the Lower Hudson, between the Troy Dam and the tip of Manhattan, have not demonstrated expected declines resulting from Upper Hudson dredging. According to EPA's own analysis, it will be over 50 years before it will be safe for New Yorkers and visitors to eat fish from the Hudson *once a week* without negative health effects. Two of EPA's sister agencies, NOAA and USFWS, have issued a study suggesting natural attenuation will take even longer.

It is simply unacceptable that New Yorkers may have to wait decades, and possibly several generations, before the Hudson River can be considered safe as a result of natural attenuation. Unless further action is taken, many of us, and even some of our children, will not live to see that time. General Electric alone is responsible for causing this

extensive damage to the river, its people, and its economic productivity. Now it is up to the EPA to require GE to do whatever is necessary to make the river whole. The first step is for the Five-Year Review to reflect the reality that the cleanup has not achieved its objectives, and require further dredging of the Upper Hudson and further investigation of the Lower Hudson.

Thank you for the opportunity to comment, and for your serious consideration of our concerns.

Protect people and wildlife, NYS deserves a Healthy Hudson River

Jose Peralta <info@Riverkeeper.org>

Thu 8/31/2017 3:15 PM

To: Gary Klawinski, Project Director, EPA <epahrfo@outlook.com>;

Aug 31, 2017

Mr. Gary Klawinski, Project Director, EPA
US EPA Hudson River Field Office, Region 2, 187 Wolf Road, Suite 303
Albany, NY 12205

Dear Mr. Klawinski, Project Director, EPA,

Mr. Pruitt, Mr. Klawinski.

As a longtime advocate for the people of New York State, I have the following comments on the U.S. Environmental Protection Agency's (EPA's) Proposed Second Five-Year Review Report for the Hudson River PCBs Superfund Site.

The Hudson is a critical resource. The PCB cleanup is not protective of human health and the environment because it is not performing as planned. We need additional dredging in the Upper Hudson River, as well as a remedial investigation/feasibility study in the Lower Hudson River.
The EPA's review must clearly state "the remedy is not protective." The report states that General Electric's (GE's) cleanup of toxic PCBs it dumped in the Hudson River does not currently protect the health of the public or the river. This indicates a necessity for more investigation in the lower 150 miles.
The economic, recreational, cultural, and scenic value of the Hudson River form the bedrock of past development and future vitality for the Hudson Valley and New York City. Because GE dumped over a million pounds of toxic PCBs into Hudson River from 1947 to 1977, a once vibrant commercial fishing industry has halted; New Yorkers want, a healthy Hudson River, our children deserve a healthy Hudson River.
The New York State Department of Environmental Conservation (NYSDEC) has also expressed its concerns with the findings in the report, stating that the significant amount of contamination left in the river threatens both the public health and the environment.
The EPA agrees that, there is a need for more investigation.
Therefore, I urge the agency to require GE to do a full remedial investigation and feasibility study of the Lower Hudson River.
The National Oceanic and Atmospheric Administration (NOAA) has stated meeting cleanup goals targets would be 60 years later than expected.
Where this to be the case, the EPA's Five-Year Review Report should make this information clear and accessible to the public, who has the right to know how much PCB contamination remains in the River today.

For the Upper Hudson River, the EPA has not yet evaluated all of the

signs that the cleanup will not meet its goals, and for the Lower Hudson River, the EPA has recognized that the cleanup is not working as anticipated, yet we do not have a plan for a prompt investigation or cleanup. It is imperative that GE takes more PCBs out of the Upper Hudson River, and in turn, devises a proper plan for the Lower Hudson River.

Thank your efforts in ensuring a healthy Hudson River for generations to come.

Sincerely,

Senator Jose Peralta

Subject: Second Five-Year Review Report for the Hudson River PCBs Superfund Site

Dear Mr. Klawinski:

National Oceanic and Atmospheric Administration, in it s role as a Natural Resource Trustee for the Hudson River appreciates the opportunity to provide comments on EPA s second Five-Year Review report. We share EPA s goal of the successful recovery of the Hudson River—a nationally significant ecological, cultural, and economic resource—from PCB contamination. Our comments are provided to further that shared goal.

Under federal Superfund law, the General Electric Company (GE) is responsible for both the remediation -- cleanup -- of the PCB contamination, and the restoration of the natural resources harmed by PCBs. The State and Federal Hudson River Natural Resource Trustees are conducting a natural resource damage assessment (NRDA) and will seek to recover damages from GE to restore the natural resources of the Hudson River on behalf of the public.

PCBs released from GE facilities on the Upper Hudson River present a serious and long-term threat to the health of the entire Hudson River ecosystem. PCBs are highly toxic, cancer-causing compounds, and have contaminated the surface water, groundwater, sediments, and floodplain soils of the Hudson River. Living resources at every level of the Hudson s aquatic, terrestrial, and wetland based food chains are contaminated with PCBs.

GE s PCBs have significantly injured the public s natural resources for over 200 miles (from the Hudson Falls plant site to the Battery in New York City, and beyond). These injuries have occurred for decades, and may span the next half century or more following completion of the remedial dredging. The trustees are committed to the timely recovery and restoration of the Hudson River such that fish and wildlife can once again thrive and all people can fully enjoy the Hudson River and all that it offers.

The EPA s s assessment of the effectiveness and protectiveness of the remedy has a connection to the Hudson River Natural Resource Trustees damage assessment, particularly with respect to the amount of time it will take for the river to recover from decades of PCB contamination and the resulting determination of future injury to natural resources. As always, our comments on the remedy seek to maximize the effectiveness of the cleanup and habitat restoration and to reduce the time to full recovery.

We commend EPA for pursuing and implementing a remedy that included the removal of significant amounts of PCBs from the Hudson River. This active removal has reduced the amount of toxic PCBs in the river.

However, we continue to have overarching concerns, including:

1. Substantial quantities and very high levels of sediment PCB concentrations left behind will continue to contaminate and adversely impact natural resources, and the human use of those resources, resulting in ongoing injury and lost uses to the public.

2. Rates of recovery appear to be overestimated for PCBs in water, sediment, fish, and the PCB load traveling from the Upper Hudson River to the Lower Hudson River. These recovery rates and residual contamination drive EPA s determination of how long it will take for the public s natural resources to recover.

Given the highly contaminated residual sediments and the optimistic recovery rates, the remedy as implemented will likely not achieve the targeted reductions of PCB levels in sediments, water and fish tissue within the timeframes originally anticipated by EPA. Further, the magnitude of contamination remaining may limit the type and amount of in-river restoration options available to the trustees, particularly in the Upper Hudson River.

3. The extended timeline for recovery of the Hudson River highlights the importance of a robust and data-driven monitoring program. As we have commented previously, the Federal Trustees have concerns regarding the adequacy of the monitoring program to provide an appropriate baseline for evaluating recovery and how the public s natural resources, including the human use of those resources, will be adversely affected.

4. EPA notes in the Five Year Review Report that the remedial work in the Upper Hudson River will have little or no beneficial impact in the Lower Hudson River. This is in contrast to the ROD assumption that PCB loading from Upper Hudson to the Lower Hudson plays a major role in recovery of the Lower Hudson River. EPA appears to have rejected this major ROD assumption with little technical basis provided in the draft FYR report.

All four of these overarching concerns relate to the timing and extent of recovery of the river. Such recovery affects future injuries, and thus has a bearing on the trustees need to pursue restoration to compensate for such injuries. Attached are additional technical comments from our membership on EPA s Second Five Year Review Team. Our aim in sharing this information is to provide EPA our best available science to help inform your decision-making regarding the effectiveness and protectiveness of the remedy.

We will continue to work with EPA to achieve our shared goal of successful recovery of the Hudson River from PCB contamination.

Sincerely,

_____

Subject: Technical Comments on EPA's Proposed Second Five-Year Review Report for Hudson River PCBs Superfund Site, May 31, 2017

In a letter to non-government organizations, the U.S. EPA (2012) committed to continue to consult with the Trustees including on the scoping, data collection, and preparation of the second Five Year Review. Subsequently, \in 2016, NOAA was invited as technical experts to participate in EPA s Second Five Year Review (FYR) Team to provide review and feedback on a variety of FYR topics. NOAA accepted this offer (Brosnan et al. 2016a) and throughout the process provided detailed analysis and feedback that was intended to improve EPA s technical analyses and transparency, so that EPA would have an informed basis for evaluating the effectiveness and protectiveness of the remedy, based on the best available science. NOAA s feedback was provided at several FYR meetings as comments, presentations and follow up letters (*e.g.*, Field et al, 2016; Field and Rosman 2016; Brosnan and Jahn 2016, Brosnan *et al*. 2016b)[1]. NOAA s technical comments on the FYR report follow.

The primary objective of EPA s Proposed Second FYR for the Hudson River PCBs Superfund Site is *to determine whether the remedial actions at the Hudson River PCBs Superfund Site (Site) are protective of public health and the environment and functioning as designed*. [2] Based on our review of the report and the underlying data NOAA believes that certain Record of Decision (ROD) assumptions (*e.g.* sediment surface PCB concentrations and mass, impact of remedy on lower Hudson, and PCB recovery rates in water, sediment and fish,) are not being met), and, as a consequence, the protectiveness expected in the ROD will be substantially delayed. A summary of NOAA s comments and recommendations follow:

[1] These submittals should be included in Appendix 12 to the FYR list of correspondence provided to EPA by NOAA or the Hudson River Natural Resource Trustees.
[2] Executive Summary pg. 1

1. **Significant amounts of elevated PCB contamination have been left in Upper Hudson River (UHR) sediments following remedy implementation which will further delay recovery of Trustee resources:**

    a. **The Upper Hudson in-river remedy leaves highly elevated PCBs in the sediment surface and at depth in the immediate vicinity of dredged areas in River Sections (RS) 2 and 3 (i.e., incomplete PCB sediment deposit removal)**

    b. **PCB mass remaining outside of dredged areas is underestimated in RS2 and RS3**

    c. **FYR estimates of monitored natural attenuation (MNA) recovery rates appear to be higher than supported by data and analyses for PCBs in water, sediment, fish, and PCB load to the LHR. Overestimation of the rate of recovery reduces the ability of EPA's models to discriminate among remedial alternatives.**

        i. **Assessment of remedy effectiveness and protectiveness should be based on measured post-dredging PCB concentrations per the ROD and not an overreliance on percent reduction in PCBs and PCB decay rates**

        ii. **The FYR reliance on retroactive data adjustment adds significant uncertainty to temporal projections of PCBs for fish and sediment**

    d. **Underestimation of Total and Tri+PCBs in sediment based on recent EPA Method 1668 split-sample analysis is not addressed in FYR**

2. **The ROD assumption that PCB loading from UHR to the LHR plays a major role in LHR recovery appears to be rejected with little technical basis provided**

3. **The 2016 surface sediment monitoring plan does not provide an appropriate baseline for evaluating sediment recovery**

NOAA's recommendations for improving the FYR are as follows:

- When calculating mass, Sediment Sampling and Analysis Program (SSAP) cores with an unclassified sediment texture should be treated as fine-grained sediments rather than gravel or bedrock as many of these cores most likely represent undredged PCB deposits.
- The post-source control period from 2005 to 2008 should be used as baseline when calculating HUDTOX-generated MNA PCB decay rates for water.
- Calculation of MNA decay rates for water should only use PCB monitoring data from the baseline monitoring sampling period because of major changes in sampling location and sample collection method.

- PCB load from the UHR to the LHR should continue to be measured in a consistent manner and a more robust analysis is required to assess the impact of the UHR on the LHR.
- The MNA period for fish should begin in 1997 rather than 1995, which is consistent with prior practice. (*i.e.*, use consistent data).
- For evaluating temporal trends in fish, use the long-term monitoring species (or species groups) and stations established by NYSDEC and restrict the size range and time of year to be consistent with NYSDEC monitoring and EPA s food web models.
- Assess the impact of using a single correction factor to adjust year(s) of fish data on the uncertainty of the temporal PCB trend analysis.
- Conduct rib-in vs rib-out comparative study for other fish species that were previously incorrectly processed using non-NYS Standard Fillet protocols.
- Increase sample size, sampling segmentation (0-2, 2-6, 6-12 inches) and spatial resolution of post-remediation sediment sampling design sufficient to create a surface weighted average concentration (SWAC) for cohesive sediment in each river pool in order to capture the highly contaminated unremediated cohesive sediment areas in RS2 and RS3 sampled in the SSAP, and treat these as a separate stratum from the non-cohesive sediments.
- Measured PCB concentrations should be the primary measure of remedy success as defined by the 2002 ROD rather than decay rates or percent reduction.
- For future PCB sample analyses, switch to EPA Method 1668 entirely (preferred option) or use a higher percentage (*i.e.*, at least 25%) of split-sample PCB congener Method 1668.
- Incorporate Hudson River Reference Material into future fish PCB analyses.
- For past data adjustments, analyze archived sediment and fish samples (or sample homogenates for fish) by PCB congener Method 1668 that had previously been analyzed using PCB Aroclor Method 8082 or the modified Green Bay Method (mGBM).

DETAILED TECHNICAL COMMENTS ON THESE POINTS FOLLOW:

Remedy leaves highly elevated PCBs in the surface and at depth in the immediate vicinity of the dredged areas in RS2 and RS3 that will significantly delay recovery of the river.

The extensive SSAP coring for the dredge area design demonstrated that surface sediment PCB concentrations were considerably higher, shallower, and more widespread than EPA expected, especially in RS2 and RS3 (Field *et al.* 2009; USEPA 2012). The majority of the highly elevated PCBs in surface sediment and PCB mass were found immediately adjacent to defined dredge areas (Field *et al.* 2011a; Field *et al.* 2011b). Approximately 175 acres surrounding the dredged areas in RS2 and RS3 exceeded the more stringent cleanup levels for RS1 for PCB mass (MPA) or surface (top 12 inches) PCB concentration (Field et al 2016). The FYR (USEPA 2017) confirmed that PCB mass within PCB contaminated sediment deposits was dramatically higher than the 2002 ROD expected. Because target cleanup levels for RS2 and RS3 were approximately 3X higher for PCB mass and surface concentrations than in RS1, the dredge areas for RS2 and RS3 surgically removed a portion of larger sediment PCB deposits, essentially removing the hole, but leaving the donut of contamination un-dredged.

FYR underestimates PCB mass outside of dredged areas.

> ***Recommendation: Treat SSAP cores with "unclassified" sediment types differently when calculating post-dredging mass, as these SSAP cores most likely consist of fine-grained sediments representative of PCB deposits.***

The FYR confirmed that PCB mass within PCB contaminated sediment deposits was dramatically higher than the ROD expected. According to Table A8-2 (USEPA 2017, Appendix 8), the ROD substantially underestimated the PCB mass in all three river sections. Overall, the observed total PCB mass removed under the Remedial Action was 223% greater than the ROD estimate from approximately the same number of acres. Total PCB mass was underestimated by 45% and 220% for RS2 and RS3, respectively. PCB mass per acre was underestimated by 26% and 349% for RS 2 and RS3, respectively. This implies that the PCB deposits had significantly more PCBs than the ROD expected. The FYR attributes the reason for these differences to *earlier estimates … based on cores that did not fully characterize the vertical extent of contamination* [3], but provides no documentation that this was the primary explanation for the differences from the ROD expectations in RS2 and RS3. According to NYSDEC, underestimation of the depth of contamination associated with inadequate core penetration was observed in RS1 but was limited in RS2 and RS3. Therefore, it is reasonable to assume that the un-dredged PCB deposits adjacent to the dredged areas in RS2 and RS3 also had higher PCB mass than the ROD expected. Further evidence is provided by our observation that sediment samples exceeding RS1 target cleanup levels in all three river sections had similar average surface (top 12 inches) PCB concentrations (19-25 mg/kg Tri+PCBs) and MPA (8-9 g/m^2 Tri+PCBs).

[3] Appendix 2, Section 4.5, pg. 4-8

The FYR generalized assumption that *unclassified areas within River Section 3… were predominately comprised of gravel and bedrock substrate* [4] increases the uncertainty of EPA s estimates of PCB mass remaining in the river. Most of the areas with multiple unclassified SSAP cores (without a sediment type classification) are located in shallow nearshore or backwater areas. These unclassified shallow nearshore and backwater areas are often adjacent to dredge areas and represent unremediated PCB sediment deposits. The 240 unclassified cores in RS3 had an average MPA of greater than 7 g/m^2 Tri+PCBs, and 148 (62%) of those cores exceeded the target cleanup levels for RS1. However, the FYR assigns the average MPA for gravel (2.5) or bedrock (0.00) as upper and lower bounds, respectively, in the calculation of PCB mass outside the dredged areas. Using a lower average MPA for unclassified cores than was actually measured leads to an underestimation of PCB mass. At a minimum, the unclassified areas represented by SSAP cores (~30 acres) should be treated as cohesive fine grain sediment in the calculation of mass remaining in un-dredged areas.

FYR estimates of MNA recovery rates appear to be higher than supported by data and analyses for PCBs in water, sediment, fish, and PCB load to the LHR.

> ***Recommendation: Consistent with prior practice, the MNA period should begin in 1997 rather than 1995.***

The FYR relies on estimated recovery rates for water, sediment, fish, and PCB load to LHR to confirm model estimates of approximately 8% per year. In most cases, as discussed below, the FYR uses data treatment approaches that result in elevated rates of recovery.

The FYR incorrectly defines 1995 as the beginning of the MNA period. Previously, EPA recognized that PCB releases from the failure of the Allen Mill gate structure and from the migration of PCB oil through the bedrock were not mostly controlled by remedial measures until 1997 (USEPA 2000a). For that reason, it has been customary to use 1997 as the starting point for pre-dredging temporal analyses. For example, for fish, the time period of 1997-2008 was used as the basis for development of pre-dredging temporal models (USEPA 2010b; Greenberg *et al.* 2010; Greenberg *et al.* 2011; Greenberg 2013).

Water

> ***Recommendation: Calculation of MNA decay rates for water from the HUDTOX model should use the post source control period from 2005 to 2008. Calculation of MNA decay rates from PCB monitoring data should only use data from the baseline monitoring sampling because of major changes in sampling location and sample collection method.***

The FYR reports that revamped HUDTOX model MNA predictions based on updated hydrologic conditions (but not updated surface sediment concentrations) forecast PCB decay rates between 9.9% and 11.7% for the four stations (Thompson Island Dam, Schuylerville,

[4] Appendix 2, Section 4.4, pg. 4-6

Stillwater, Waterford) considered (USEPA 2017, Appendix 1, Table A1-7). These estimated PCB decay rates are considerably higher than the reported data-based rates for Stillwater and Waterford for the same 1995-2008 time period. Unfortunately, neither the MNA predicted decay rates nor the data-based decay rates should be taken at face value. The HUDTOX model incorporated a 6-fold drop in upstream water concentration (from 0.16 kg PCB/day to 0.0256 kg PCB/day) occurring January 1, 2005 (USEPA 2002). Calculating a decay across that step-wise drop in PCB input concentration provides more information on source control at the two GE plant sites than on natural recovery of UHR sediments (Field and Rosman 2016). Between 2005 and 2008, a period of natural recovery, NOAA calculated PCB decay rates for the four stations using data from the revamped model (USEPA 2017, Table A1-7) that are considerably lower than reported in the FYR, ranging from 0.01% to 5.5%.

The FYR evaluation of the water column data-based decay rates does not account for the PCB releases from the failure of the Hudson Falls Allen Mill gate structure in 1991 and from the migration of PCB oil through the bedrock. Although not as marked as during the initial period of GE s Allen Mill release, the continuing impact to PCBs in the water column is evident from the Rogers Island water column monitoring data (see Attachment, Figure 1---plot of Rogers Island water data provided by NYSDEC with the period between 1995 and 1997 highlighted for emphasis). Additionally, the FYR analysis does not account for major changes in sampling location (*e.g.*, Thompson Island station moved from nearshore to mid-channel) and method (shift to automated samplers) beginning in June 2004 with the initiation of GE s baseline monitoring program. The high variability, compounded by differences in sampling location and methods, makes the currently available surface water data an unreliable measure of temporal change in PCBs.

PCB load to LHR

Recommendation: NOAA supports the recommendation of the Hudson River Foundation report (Farley et al 2017) to re-instate the USGS suspended sediment monitoring at Waterford and to collect additional high flow samples to improve evaluation of PCB loading to the LHR.

The measured PCB load to the LHR between 2004 and 2008 was 2 to 3 times greater than the original HUDTOX projections (USEPA 2010a; Hydroqual 2010). In the FYR, EPA updated the HUDTOX model projections with observed flows and estimated tributary flows and solids loads through 2008, but did not update the sediment concentrations with SSAP data. The updated HUDTOX model projections in the FYR (USEPA 2017, Appendix 1, Table A1-8) improved the model-data comparison, but still underestimates the measured 2004-2008 PCB loads by 8-41%, with the difference increasing with time. Based on data provided in the FYR (USEPA 2017, Appendix 1, Table A1-8), the updated HUDTOX model predicts PCB load to the LHR between 2004-2008 will decrease at a rate of 9.2%, while the estimated decay rate from the measured PCB load has a decay rate of 2.8% [Attachment 1, Figure 2]. This shows that, prior to dredging, PCB loading to the LHR was declining at a much slower rate than the updated HUDTOX model predicted.

Sediment

Recommendation: The comprehensive sediment sampling data from the SSAP should be treated as the baseline for evaluating recovery of PCB-contaminated cohesive sediment in un-dredged areas. Studies conducted since the SSAP (Downstream Deposition study 2011-3 and 2016 post-dredging sediment study)* mostly do not address the *highly PCB-contaminated cohesive sediment areas adjacent to dredged areas in RS2 and RS3 and should not be used as a measure of sediment recovery without significant caveats. Sediment grain size data should be used to reduce the uncertainty in defining cohesive sediment areas.

EPA s 2002 ROD assumed that implementation of the selected remedial alternative REM 3/10/S would result in post-dredging surface sediment concentrations in RS2 and RS3 less than or equal to 1 ppm Tri+PCBs in cohesive sediment, comparable to post-dredging surface sediment concentrations in RS1. EPA (USEPA 2010b) confirmed the finding of Field *et al.* (2009) that pre-dredging surface sediment concentrations were *much higher than model predictions* [5] and *exceed the upper bound of model predictions*. [6] As discussed earlier, the highly elevated PCBs in surface sediment in the SSAP samples were mostly immediately adjacent to dredge areas. Unfortunately, the surface sediment surveys conducted since the SSAP data collection (Downstream Deposition Study (DDS) 2011-3 and 2016 post-dredging sediment study) provide data that are not directly comparable to the SSAP data (very limited data collected from the highly contaminated cohesive sediments surrounding the dredge areas and only sampled the top 2 inches and not the top 12 inches of surface sediment used to define dredge areas). In addition, the analysis of split sediment samples in 2016 using the current EPA standard method for PCB congener analysis (Method 1668) indicates that the PCB Aroclor analysis (Method 8082) for those studies significantly underestimated Tri+ and Total PCBs.

The surface sediment PCB concentrations for cohesive sediment in RS2 and RS3 estimated from the DDS sediment survey and 2016 sediment monitoring survey should be considered to be biased low. The DDS survey used a biased sampling design to specifically focus on the downstream edge of dredge prisms. According to EPA (USEPA 2016), *If assessing changes in conditions for the entire river section were the DQO, then care would have been taken to ensure that the distribution of the PCB concentrations targeted by the DDS program would have been a representative subset of the SSAP program*. This was clearly not the case for RS2 and RS3. The sample locations selected for comparison to nearby (within 20ft) SSAP locations outside of dredge areas represented locations that had PCB concentrations that were significantly higher than the results for all SSAP locations for RS2, and the median PCB concentration was higher than the 95% UCL for all SSAP locations in RS3. Attempting to re-sample high concentration

[5] USEPA (2010b), pg. I-53
[6] Ibid.

samples from a lognormal distribution has a high statistical probability that the re-sample result will be lower than the original sample (Field et al. 2015).

The FYR uses the side-scan sonar results from 1992 to classify the UHR bottom sediment type, rather than using the GE results from the SSAP. Because the Reassessment bottom type mapping did not cover RS3, EPA chose to create a model to predict sediment type in RS3 from the GE data. The 2016 samples are classified into cohesive and non-cohesive samples based on this predictive model, which adds considerable uncertainty to the classification, in spite of the fact that sediment grain size analysis on the 2016 samples was available for classification. In the baseline modeling report (USEPA 2000b), samples with at least 25% fines (silt + clay) were classified as cohesive sediment. Only about 1/3 of the samples identified as cohesive by the predictive model for RS3 had at least 25% fines and more than 20% had sediment texture classified by the field samplers as coarse or rock. Including samples with a much lower percentage of fines likely underestimates the PCB concentration in cohesive sediments. For example, identifying cohesive sediment based on grain size analysis in RS3, the arithmetic mean Tri+ PCB concentration is 1.3 (mg/kg) compared to 0.8 as reported in the FYR (USEPA 2017, Appendix 4, Table A4-3). These concentrations do not take into account the underestimation of PCB concentration by the Aroclor Method (discussed elsewhere in this document). The adjusted mean cohesive sediment Tri+ PCB concentration in RS3 is 4.2 (mg/kg), based on the correction factor from the split-sample Method 1668 analysis.

Fish

> ***Recommendation: For evaluating temporal trends, use the long-term monitoring species (or species groups) and stations established by NYSDEC and restrict the size range and time of year to be consistent with NYSDEC monitoring and EPA's food web models. Use only lipid-normalized data to evaluate temporal trends and for comparison to food web model projections use wet weight values adjusted to the standard lipid content for each fish species used in the modeling. Assess the impact of using a single correction factor to adjust year(s) of PCB data on the uncertainty of the temporal fish trend analysis. Conduct rib-in vs rib-out comparative study for other fish species incorrectly processed using non-NYS Standard Fillet protocols. Collect sufficient spatial data to analyze fish concentrations on a pool by pool basis, rather than river section basis.***

Evaluation of temporal trends in fish PCBs requires consistent sampling for fish species from specific sampling locations over time. Because PCBs in fish are strongly associated with lipid content and lipid content has decreased in spring-collected resident species, analyzing temporal trends should take into account lipid content and not rely on wet weight concentrations. Prior to the GE s implementation of the baseline monitoring plan (BMP) in 2004, all fish data were collected by NYSDEC from 2 regular monitoring stations in the UHR Thompson Island Pool (RS1) and Stillwater (RS3) for spring-collected resident species (bullhead, black bass, yellow perch) and fall-collected forage fish (yearling pumpkinseed). In the LHR, 3 regular monitoring locations (Albany/Troy, Catskill, and Poughkeepsie) for the same species with the addition of white perch. These species/locations represent the most robust and consistent dataset to evaluate

temporal trends. In contrast, the BMP sampled multiple locations in each river section in the UHR. By including all BMP sampling locations from RS1 and RS3, the FYR overweighs the data from the BMP (2004-8) and adds significant uncertainty by including the additional stations. The variability among stations within river sections is clearly evident in Greenberg *et al.* (2010, 2011). The other species used in the FYR fish trend analysis were inconsistently sampled throughout the time period and not suitable for long-term PCB temporal trend analysis.

The FYR temporal analysis does not account for rib-on /rib-off difference for lipid-normalized PCBs. Based on an unpublished special study for black bass (largemouth and smallmouth bass), the FYR minimizes the effects of GE s change in fillet processing protocol by excluding the 2007-8 fillet samples from temporal trend analysis for wet weight PCBs. Lipid-normalized results were assumed to be unaffected by this change, in spite of the fact that average lipid-normalized concentrations for rib-on fillets in black bass were ~22% higher (13-31% 95% confidence interval) than the rib-off samples and would require a correction factor analogous to the FYR homologue adjustment factors. Additionally, the FYR assumes, with no supporting data, that the special study results for black bass apply equally to all other fillet species (*e.g.*, bullhead, yellow perch, white perch, catfish, and striped bass) (Brosnan *et al.* 2015; Brosnan and Jahn 2015; Brosnan *et al.* 2016). Including the 2007-8 lipid-normalized fillet data, which is biased low by an unknown degree, results in an inflated temporal decay rate for those species.

The homologue correction factor used in the FYR for NYSDEC data from 1999-2011 uses the wet weight adjustment factor for the lipid-normalized results, in spite of the fact that both NY and GE labs analyzed lipid along with PCBs and the correction factors for the lipid-normalized concentrations were different. NYSDEC data during the MNA (pre-dredging) period from 1999-2003, before GE began sampling in 2004 for the baseline monitoring program, was inflated by this approach, because the wet weight correction factor used by EPA was 1.17 compared to a lipid-normalized correction factor of <1 (0.96). This inflates the NYSDEC data during the period from 1999-2003 before GE began sampling in 2004 for the baseline monitoring program and effectively increases the estimated temporal decay rate.

Using only the lipid-normalized PCB data from the principal monitoring stations, species or species groups, and MNA time-period from 1997-2006 (excluding data from 2007-8 when GE incorrectly processed fillet samples), NOAA calculated exponential decay rates using the original (unadjusted) data, the FYR-adjusted data, and modifications to the FYR adjustment factors for NYSDEC fish data that incorporated the lipid-normalized adjustment factors (discussed above) (Table 1). The PCB decay rates vary somewhat among the 3 data approaches, but the overall conclusions are much the same. In the UHR, only black bass and yellow perch from the Thompson Island Pool monitoring station show PCB decay rates greater than 8%. Bullhead (the species most closely associated with the sediment) and yearling pumpkinseed from that same location have PCB decay rates of less than 5% and 0%, respectively. At the other UHR long-term monitoring locations in the Stillwater Pool, all species had PCB decay rates less than 5%.

At the Albany/Troy location all species except pumpkinseed had PCB decay rates of 4% or less. Pumpkinseed showed a very high PCB decay rate at Albany/Troy, but the sampling location was changed several times during the time period. Because pumpkinseed are known to show high site fidelity, the changes in sampling location makes those results for pumpkinseed highly unreliable. Other locations in the LHR (Catskill and Poughkeepsie) showed similarly low PCB decay rates. Overall those results were very consistent with findings of Field et al (2016) based on emulation of the HUDTOX-FISHRAND models for the LHR applying updated surface sediment concentrations.

The sampling program was designed to determine PCB concentrations in fish by river section rather than each river pool. The river pool sampling approach for fish (sediment and water) is essential to establishing a post-dredging baseline for evaluations of fish exposure in the UHR and LHR. Resident fish tend to remain within a river pool, which means they integrate their exposure within pools or smaller areas, and not over much larger river sections (Field and Kern 2009b).

FYR appears to reject ROD assumption that PCB loading from UHR to the LHR plays a major role in LHR recovery

Recommendation: Need a more robust analysis of impact of UHR on LHR.

The FYR appears to disregard prior conclusions and modeling results in the ROD (USEPA 2002) that the UHR PCB load to the LHR is the primary factor in the recovery of LHR fish. The FYR cites slower recovery of LHR fish as evidence that the UHR does not play an important role in LHR and speculates about other sources . Based on high-resolution core sampling data and modeling (Thomann *et al.* 1989, Farley *et al.* 1999, USEPA 2000a, Hydroqual 2007, Rodenburg and Ralston 2017), the primary source of PCBs to the LHR is the result of past and continued loading of PCBs originating from the Hudson Falls and Fort Edward plant sites and sediments within the UHR.

EPA concluded in their Phase 1 report (p. I-4) that,

> *The observed baseline loads to the Lower Hudson prior to dredging were substantially greater than the model forecast of Monitored Natural Attenuation (MNA) and show very little decline. The loads to the Lower Hudson River under MNA will be substantially greater than those forecast by the model by approximately 6,000 kg over 25 years. Also the surface sediment concentrations in the Upper Hudson River remain elevated despite the passage of time and continue to provide a greater reservoir of contaminated sediments for transport to the Lower Hudson than was envisioned when the remedy was selected*.

Post-dredging, as pointed out previously, most of the remaining sediment PCB contamination is found in RS2 and RS3. Based on GE s modeling, Connolly *et al.* 2000 pointed out the importance of sediment remediation in RS2 and RS3 in reducing PCB loading to the LHR:

Sediment remediation in the TIP would be less effective at reducing PCB flux to the Lower Hudson River in the short term than would remediation of sediments downstream of the TIP.

There appears to be little basis to reject the ROD s assumption that UHR sediment PCBs are a major factor in the recovery of LHR fish, given the higher than expected PCBs in surface sediment and the much slower decline of PCB loading to the LHR.

2016 surface sediment monitoring plan provides inadequate baseline of PCBs for evaluating sediment recovery.

> ***Recommendation: The sediment monitoring program should be modified to adequately address the highly contaminated sediments in RS2 and RS3, which will remain a major source of PCBs to Upper Hudson food webs and provide continued PCB loading to the LHR. The highly contaminated cohesive sediment areas sampled during the SSAP should be treated as a separate stratum from the non-cohesive sediments and more samples are needed within those cohesive areas per river pool to establish a surface sediment baseline for evaluations of fish exposure, PCB loading to the Lower Hudson River, and the rate of recovery of the system. Core samples should be collected and analyzed from 0-2, 2-6, and 6-12 inch intervals consistent with the definition of "surface" as the top 12 inches in the ROD (USEPA 2002) and confirmed in the Final Dispute Resolution (July 26, 2004).***

EPA s 2016 sediment sampling plan is intended to provide a baseline for future monitoring to determine the rate of recovery in surface sediment. The underlying premise assumes that a SWAC for each entire river section is the best metric for evaluating recovery. The modeling done by EPA to support the ROD (and by GE) is based on the understanding that cohesive (fine-grained) sediment provides the foundation for the food web (NOAA 2016). However, the 2016 sediment sampling, by virtue of the design, provides only minimal information on the known highly contaminated unremediated areas (mostly cohesive sediments) surrounding the RS2 and RS3 dredge areas that were identified in the SSAP. Therefore, the 2016 sediment sampling provides an inadequate post-dredging baseline.

Cohesive sediments represent the primary source of exposure to the benthic food web and fish species, but most of the 2016 samples were collected from non-cohesive sediment areas. The highly contaminated cohesive sediment areas sampled during the SSAP should be treated as a separate stratum from the non-cohesive sediments and more samples are needed within those cohesive areas to properly characterize them.

The sampling program was designed to determine the PCB SWAC by entire river sections rather than the smaller river pools (=river reach). The river pool sampling approach is essential to establishing a surface sediment baseline for evaluations of fish exposure, PCB loading to the Lower Hudson River, and the rate of recovery of the system. Resident fish tend to remain within a river pool, which means they integrate their exposure within pools or smaller areas, and not over much larger river sections (Field and Kern 2009b).

The 2016 sediment sampling only collected the top 2 inches of surface sediment, but it is important to measure PCBs in the top 12 inches of sediment. Surface sediment was defined in the 2002 ROD and in the Final Dispute Resolution (July 26, 2004) as 0-12 inches. The PCBs in

the top 12 inches represent a more complete accounting of the PCBs biota are or may be exposed to in the future, as well as the mass that may be transported to the lower river. In the dispute resolution EPA acknowledged that *The Agency selected a remedy that targeted dredge areas based on, among other things, PCB concentrations representing the top 12 inches of sediment in order to account for all processes – whether physical, chemical or biological - that can make PCBs bioavailable*.

According to the FYR: *One year of post-dredging data indicate a reduction in exposures consistent with EPA's expectations at the time of the ROD.* [7] EPA s 2016 sampling plan, which is proposed to serve as the baseline for future sediment sampling to assess temporal change, only minimally addresses areas of known highly contaminated sediments in cohesive sediments adjacent to dredge certification units (*see* NOAA 2016 comments on plan). Consequently, the sediment monitoring program will not adequately address these highly contaminated sediments in RS2 and RS3, which will remain a major source of PCBs to Upper Hudson food webs and provide continued PCB loading to the LHR. The 2016 sediment monitoring plan also provides an inadequate basis to *indicate a reduction in exposures consistent with EPA's expectations at the time of the ROD.*

NOAA s 2016 comments on the Operation, Maintenance, and Monitoring Plan (OMM) 2016 summarize the concern:

> Both EPA s and GE s bioaccumulation modeling recognized that fine-grained (cohesive) sediments were a major source of exposure for PCBs entering the food web. For example, the EPA bioaccumulation modeling assumed that fish were primarily exposed to cohesive sediment (75%) while in GE s bioaccumulation models [QEA 1999], PCB concentrations in the food web were based entirely on exposure to cohesive sediments. Most vegetation in the Upper Hudson is found associated with fine-grained sediments.
>
> The OMM Plan is not comparable to any historical data, and does not provide sufficient sampling power to address individual reaches in RS2 & RS3, which will provide necessary spatial resolution to measure recovery. Using statistical analysis of DDS data as the basis for sample density underestimates number of samples required for RS2 & RS3 because it doesn t take into account composite sampling in the DDS in RS2 and RS3.
>
> Focusing exclusively on the top 5 cm instead of the bioactive zone of 30 cm (as defined in the EPA-GE Dispute Resolution) provides limited information on the PCBs in the surface that will be available to biota and at potential immediate risk of recontamination of dredged areas and transport to the LHR.

[7] Pg. 67.

FYR assessment of remedy effectiveness over-relies on percent reduction and decay rates rather than actual PCB concentrations

> ***Recommendation: Actual PCB concentrations should be the primary measure of remedy success as defined by the ROD rather than decay rates or percent reduction. The FYR should acknowledge that the highly contaminated areas adjacent to the dredged areas in the SSAP have not been re-sampled sufficiently to determine post-dredging PCB concentrations, percent reduction, or decay rates.***

The FYR emphasizes the percent reduction in PCB mass in the river. The success of the remedy does not depend on the percentage or amount removed, but the magnitude and spatial extent of PCBs left behind, which greatly exceeded expectations in the 2002 ROD. The FYR underestimate of ~60,000 kg PCB mass left behind outside of dredged areas is almost equivalent to the 70,000 kg PCBs the 2002 ROD estimated would be removed from the river by the dredging remedy.

The FYR compares SSAP and 2016 surface sediment data from the top 2 inches to estimate reduction in surface area PCB concentration. This is an apples to oranges comparison, as the 2016 data only minimally included samples in RS2 & RS3 from the highly elevated fine-grained PCB sediment deposit areas adjacent to dredged areas. Additionally, 2016 PCB Aroclor analysis significantly underestimated PCB concentrations based on split-sample analyses (see EPA Method 1668A discussion, below).

Important implications of split-sample PCB analysis are not addressed in FYR.

> ***Recommendation: In future PCB analyses switch to Method 1668 entirely (preferred) or use a much higher percent of split-sample EPA Method 1668 (Method 1668). Incorporate Hudson River Reference Material into future fish PCB analyses. For past data adjustments, analyze archived sediment and fish samples (or sample homogenates for fish) that had previously been analyzed using Aroclor and/or mGBM methods.***

The 2016 sediment sampling included analysis of a subset of the samples by a highly qualified independent laboratory using the current standard for PCB congener analysis (EPA Method 1668A) (Anchor QEA 2017). However, the FYR report does not contain an analysis of these results. NOAA s evaluation indicates that Total PCBs (and Tri+ PCBs) measured by EPA Method 1668A congener analysis were more than twice as high as the Arcolor Method 8082 (geometric mean ratio of 2.4) previously used by Pace laboratory (formerly NEA, GE s contractor for laboratory analysis). This implies that recent previous sediment analysis conducted by GE s Pace laboratory (*e.g.*, DDS 2011-3 analyses) (and possibly earlier analyses conducted by NEA such as SSAP) underestimated PCBs in the sediment. The modified Green Bay Method (mGBM) split-extract analysis conducted by NEA during the last 3 years of the SSAP sampling indicated that the Aroclor total PCB concentrations in sediment were higher than reported from the mGBM peak analysis (USEPA 2017). The 2016 results suggest that the mGBM peak analysis may have also underestimated PCB concentrations in sediment.

Although comparable split-sample data from Method 1668 for fish do not exist, it is reasonable to hypothesize that total PCB concentrations for fish may also have been underestimated. This uncertainty could have been avoided if GE had used the Hudson River Reference Material (HRM) prepared by NYSDEC, as required by the Consent Decree. NYSDEC contract labs have been using the HRM routinely since 2009.

To evaluate the potential implications of this major uncertainty, NOAA recommends that EPA send previously analyzed and archived frozen fish samples to the same laboratory that EPA used to analyze the 2016 sediment-samples using Method 1668 (Axys Laboratory) for PCB congener analysis using Method 1668 that have prior PCB analyses by both Aroclor and mGBM methods and include both the Hudson River Reference Material[8] and Standard Reference Material available from the National Institute of Standards and Technology (NIST) or a commercial vendor.

Homologue adjustment of fish PCB data and estimating sediment type for RS3 adds major uncertainty to the FYR evaluations

> ***Recommendation: Assess the impact of using a single correction factor to adjust multiple years of fish PCB data on the uncertainty of the temporal PCB trend analysis. Confirm that Total PCBs in fish from mGBM are comparable to Total PCBs from Method 1668.***

The FYR s homologue adjustment of NYSDEC and GE fish data uses a single factor based on a geometric mean of the ratio of Aroclor PCBs to mGBM Total PCBs. In the case of the NYSDEC data, the adjustment factor from 1999-2000 is applied to all subsequent years without any data to document applicability. The NYSDEC adjustment factor applies the factor from wet weight analysis to the lipid-normalized concentrations, instead of more appropriately using the factor from lipid-normalized analyses, which are substantially different for some years. Also, for the 1997 NYSDEC fish data, the FYR relies on a model-estimated factor from Butcher *et al.* .(1998), ignoring the data from the split-sample approach used for subsequent years. Using a single factor ignores the uncertainty/variability of the relationship for different subgroups (e.g., species, location, year) and may not represent the pattern in the underlying data. Additionally, the 2016 split-sample analysis for sediment suggests that both the Aroclor and mGBM PCB analyses may significantly underestimate the total PCB concentration from full congener analysis (Method 1668).

> ***Recommendation: Use direct measurement (i.e., sediment grain size analysis) to determine cohesive/non-cohesive sediment type in monitoring sediment.***

The FYR relies on side scan sonar surveys conducted in 1992 to determine sediment type rather than the side scan sonar surveys conducted by GE in 2004 to design the remedy. Because the

[8] "Performance evaluation (PE) samples for fish tissue, in the form of the Hudson River Reference Material (HRM) developed by New York State, shall be incorporated into the program. EPA will consider removing the MS/MSD samples if the HRM material is incorporated." From Appendix B to the Consent Decree, Hudson River PCBs Site, Statement of Work (SOW) for Remedial Action and Operations, Maintenance and Monitoring, December 2010, Section 2.7.5 Measurements.

1992 sediment type analysis did not include RS3, the FYR developed a predictive model of sediment type to determine cohesive/non-cohesive areas in RS3. The model was estimated to accurately predict cohesive/non-cohesive locations 76% of the time. As discussed earlier, a number of samples from the 2016 sediment sampling were incorrectly classified as cohesive based on grain size analysis or sediment texture observations, which results in an underestimation of the PCB concentration in cohesive sediment. Given the importance of the cohesive sediment in estimating sediment recovery and PCB mass, using a model rather than direct measurement increases the uncertainty of the estimates.

Conclusion

In conclusion, NOAA appreciated the opportunity to serve on EPA's FYR panel and to provide technical comments on the draft FYR report. NOAA shares the goal of full recovery of the river from PCB contamination in as short a time as is practicable and commend EPA for the significant dredging that has been achieved. Our technical comments are intended to improve EPA's ability to more accurately assess remedy protectiveness and effectiveness, including the time for the river to fully recover, based on the best available science. Our comments include observations that major ROD assumptions are not being met (*e.g.*, levels and amount of PCBs left behind in sediment and other environmental media, rate of recovery, and impact of the remedy on the LHR), that recovery will be significantly delayed from what was anticipated in the ROD, recommendations on how to improve data analysis, and the need for a much more robust monitoring program to assess protectiveness and effectiveness in future. Please do not hesitate to contact us with any questions or comments or if you would like to discuss these recommendations further.

Sincerely,

Mr. Gary Klawinski, Director
EPA Region 2 Hudson River Office
187 Wolf Road, Suite 303
Albany, NY 12205

Dear Mr. Klawinski,

I am submitting my comments on the Hudson River Superfund Draft Second Five Year Review on behalf of the New York State Bridge Authority.

The Bridge Authority has responsibility for five spans that link the two shores of the Hudson River. These beautiful and historic structures stretch from the Bear Mountain Bridge in the Hudson Highlands to the Rip Van Winkle Bridge at the foothills of the Catskill Mountains, and include the dramatic Mid-Hudson Bridge, just down the hill from here. All of the bridges link the communities of the region and contribute to its cohesive economy.

But the river that flows beneath these bridges—and back and forth with the tides in the 66 miles between them—is part of one of the nation's largest Superfund sites, contaminated by toxic PCBs that imperil public health, the environment, people's enjoyment of the river and economic opportunity.

It is my understanding that your draft Five-Year Review acknowledges that GE's cleanup hasn't achieved the goals you set to restore the river's health, but states it will ultimately achieve the goals of those goals in 53 years, a claim that is challenged by other federal and state agencies. I understand that a large quantity of PCBs remains in the upper Hudson that will continue to pollute the river north of Troy and contaminate the lower river. I urge you to issue a Final Five Year Review that deletes the claim that the remedy will be protective and that lays the groundwork for additional action to ensure -- beyond doubt -- that the entire river will be healthy and safe, so the economy of the region can be restored.

I also urge you to evaluate the success of the cleanup by strict adherence to the timeframes in the cleanup plan within which fish consumption advisories were expected to be relaxed. I have a young son, and it pains me that I am not able to tell him with confidence that – at least when he is my age – he and all his family will be able to safely eat fish from the Hudson. It is unacceptable that he may not be able to safely eat fish from our river within his lifetime. Your Five Year Review can and must honestly address this problem.

FW: Supplemental Comment on the Hudson River Five Year Review Report

Subject: Supplemental Comment on the Hudson River Five Year Review Report

Hello, Gary;

I am sending this email and the attached Excel spreadsheet to supplement the comments provided earlier this week by letter from Commissioner Seggos to Administrator Pruitt.

The attached spreadsheet contains calculations of fish PCB concentrations over time in the upper Hudson River.

I chose the period from 1995 to 2003 for a few reasons: (1) By 1995, the primary IRMs had been in place at the two GE plant sites and the major releases were under control, and (2) the data are all from the DEC monitoring program, which had consistent sampling, processing, and analytical protocols. Due to the change in sampling with the start of the baseline monitoring program in 2004, with new sample locations, new labs, and new sample preparation team, and the lack of a quantified basis (such as use of the Hudson Reference Material or similar standard material) to compare the DEC and GE data to see if they were comparable, I believe a trend analysis using these years was best.

(Perch data were not available for 1995 and 1996.)

Only two locations are available for the DEC monitoring program over this period. The data were looked at from Coveville (now called SW3) and Griffen Island (now called TD5). At each location, four species were evaluated – Pumpkinseed (PKSD), Black Bass, Perch, and Ictalurids (primarily Brown Bullhead). At each location and for each species, a separate calculation was done using the annual mean original DEC Lipid Based PCB concentration, and the annual mean EPA Homologue Equivalent (called here EPA-Transformed).

The data were also looked at by using the simple linear regression tool in excel to generate an equation for each set of data, and rates of decline were generated using that equation. This was done to avoid any possible bias or “luck” in selecting high or low starting or ending data points among the data set.

All in all, 32 rates of decline were generated in the calculation. There was very little difference between the average rates of decline between the rates generated from directly from the data and from the simple regression; there was some difference

between the rates generated using the original vs. the transformed data, with the transformed data typically showing lower rates of decline.

Overall, the data can be summarized as follows:

Mean annual rate of decline in fish LPCB concentrations (data) – 2.45% (4.01% DEC data, 0.88% EPA transformed data)

Mean annual rate of decline in fish LPCB concentrations (regressions) – 2.53% (4.08% DEC data, 0.97% EPA transformed data)

The annual rates of decline ranged from a high of 8.40% (PKSD at Coveville, DEC data), to seven results showing increases in fish LPCB (negative declines).

These results indicate that EPA should take the following into account in finalizing the Five Year Review Report:

1) The observation by EPA that the rates of decline prior to remediation in fish PCB concentrations in the upper Hudson were robust, and were between 12% and 20% is not supported by the DEC fish samples collected prior to remediation.
2) The overall rate of decline in fish PCB concentrations in the upper Hudson prior to remediation was very likely less than 5%, and typically 2-3%.
3) The overall rate of decline in fish PCB concentrations in the upper Hudson prior to remediation do not support the hypothesis that there will be a robust post remedial decline in fish PCB concentrations, or that the rates of decline after remediation will allow for the targeted reductions in fish PCB concentrations to be met.
4) The rates of decline in fish PCB concentrations were properly portrayed in the ROD (see ROD figures 6-2 and 6-3, and the text on page 25, 3rd paragraph).

You can contact me if you have any questions or wish to discuss theses comments or the attached spread sheet. Please include this email and the attached spreadsheet in the administrative record for this site and in the compilation of public comments on the Five Year Review Report.

Thanks,
Kevin

June 7, 2017

Ms. Catherine McCabe
Acting Regional Administrator, Region 2
United States Environmental Protection Agency
290 Broadway
New York, NY 10007-1866

Dear Administrator McCabe,

I write to convey New York State's immediate concerns with the US Environmental Protection Agency's (USEPA) recently released Five Year Review report on the Hudson River PCBs site, and more specifically, to formally request an extension of the public comment period to 90 days.

The New York State Department of Environmental Conservation (DEC) is in the process of carefully reviewing the nearly one thousand pages of documents associated with the draft Five Year Review report and will provide a detailed response once our review is complete. However, a thirty day comment period is insufficient to provide for a careful analysis of the information and respectfully urge for this comment period to be extended.

DEC steadfastly maintains a significant amount of PCB contamination remains in the Hudson River and rejects USEPA's conclusion that the remedy is protective of public health and the environment. To be clear, DEC has concluded that USEPA-led cleanup of the Hudson River is incomplete and the findings of the USEPA's draft Five Year Review Report are unacceptable and not based on science.

Current data continues to show that significant PCB contamination is still present in the River posing a threat to human health and the environment. Based on this information, the EPA should amend its conclusion in this five year review and find that the current remedy is not protective of public health and the environment. Furthermore, in light of USEPA's refusal to work with DEC to conduct additional sampling of the River to adequately determine the effectiveness of the cleanup, New York State is moving forward on its own with a sampling program this summer.

We appreciate your consideration of this request for an extension of the comment period, and will be providing additional detailed comments outlining our concerns on the five year report in the near future.

Sincerely,

Basil Seggos
Commissioner

Subject: FW: Correspondence from Commissioner Basil Seggos Re: Hudson River Five Year Review

Hello, Gary;

See attached FYI.

I listened to your voice mail but was unable to leave you a message (full mailbox). However, in response to your questions, sometimes folks speak beyond their brief.

See you tomorrow,
Kevin

OFFICE OF THE COMMISSIONER

New York State Department of Environmental Conservation

August 30, 2017

Mr. Scott Pruitt
Administrator
Environmental Protection Agency
1200 Pennsylvania Avenue, N.W.
Washington, D.C. 20460

Dear Administrator Pruitt:

I am sending this letter to provide the United States Environmental Protection Agency (EPA) with comments of the New York State Department of Environmental Conservation (DEC) to EPA's "Proposed Second Five Year Review Report for Hudson River PCBs Superfund Site," dated May 31, 2017.

EPA states in the proposed report that the remedy will not achieve its ultimate objective for the foreseeable future, and will only become protective "at some point" in time more than 55 years from now. This is unacceptable – a remedy that will take generations to safeguard public health and the environment is clearly not protective. It is also not what the people of the State of New York were promised when EPA announced its remedial decision for the Hudson River in 2002. At that time, EPA predicted that the dredging remedy would result in rapid reductions in PCB levels in fish so that fish consumption restrictions could be relaxed in five to ten years, as opposed to many decades as is now predicted.

Moreover, despite DEC calling for EPA to conduct additional sampling, EPA has disregarded the need for more data to determine the effectiveness of the remedy. EPA appears desperate to come to a conclusion which simply is not supported by the current conditions of the Hudson River. It is obvious that the remedy is not protective of public health and the environment.

As described in the enclosed technical commentary, and as stated in the DEC report provided during EPA's five-year review process with my December 20, 2016 letter, DEC disagrees with EPA's proposed protectiveness determination for this site. The most important criterion for evaluating protectiveness is the degree of human health and ecological risk posed by the site. EPA is fully aware that the current human health and ecological risks in both the Upper Hudson River, where the remedial work was done between Fort Edward and Troy, and the Lower Hudson River, south of the Federal Dam at Troy, are well in excess of EPA's acceptable risk range. Given the current and anticipated conditions for this site, along with EPA's own guidance on protectiveness determinations, the only reasonable conclusion that can be reached is that the remedy is "Not Protective."

EPA should follow the process laid out in the 2002 Record of Decision (ROD) for this site. The remedy selected by EPA in the ROD called for targeted environmental dredging, followed by "Monitored Natural Recovery." While EPA recognized that some PCBs would be left behind in the river, EPA erroneously estimated that a sufficient amount of contaminated sediment would be removed to allow for gradual natural processes, such as the influx of cleaner sediments into the system, to reach the remedial targets identified in the ROD for rapid reductions in human health and environmental risk.

However, because greater levels of PCBs were found in the river both during project design, and again during project implementation, significantly more PCBs were left behind than was intended when EPA selected remedy. The additional sediment sampling that DEC has nearly completed (after EPA and General Electric (GE) refused to take action) will quantify how much contamination was left behind. EPA has never considered adjusting the remedial work to take the increases in known PCB mass into account, and has not provided any satisfactory scientific rationale for dismissing such consideration. As a result, it is a near certainty that the targeted reductions in fish PCB concentrations required by the ROD will not be met throughout the Upper Hudson River in the near term. Rather, as described in EPA's previous five-year review report in 2012,[1] there will likely be delays in recovery as a result of more PCBs being left behind than anticipated.

EPA should perform the data gathering and analyses necessary to confirm the assumption being made by EPA that the amount of remedial work done to date will be sufficient to reach the remedial targets set in the ROD, the first of which is to be met in 2020. As described in the enclosed detailed comments on the proposed report, there is no valid reason for EPA to modify or abandon the targets for reductions of PCB levels in fish from the ROD. EPA's unwillingness to fulfill its commitments to New Yorkers is unacceptable.

Furthermore, if the targets are not to be met, EPA must direct that sufficient additional remedial work be done. To date, EPA's persistent refusal to collect and analyze a full array of data has run counter to EPA's original commitment to clean up the site. In order to perform the necessary evaluations, EPA should ensure the collection of sufficient water, sediment, and fish data to fully assess whether the remedy will meet the targets in the ROD, starting with the initial target of 0.4 ppm PCBs in fish by 2020. As indicated above, DEC raised the need for EPA to conduct additional sediment sampling in November of 2016. EPA formally rejected that request in December of 2016. DEC then took the necessary steps to begin taking its own sediment samples over the summer. Similarly, if EPA refuses to conduct additional fish sampling, DEC will do so.

---

[1] First Five Year Report for the Hudson River PCBs Superfund Site, June 1, 2012 available at https://www3.epa.gov/hudson/plans.html

As you know, the targets in the ROD for rapid reductions in human health and ecological risk were the primary bases upon which EPA justified the dredging remedy. These same targets were the primary bases for the State to concur that the remedy would be protective of public health and the environment. EPA rejected (as the State rejected) remedial alternatives which would have resulted in delays in recovery of 10 or more years, as EPA recognized at the time of the ROD that the controls on risk, such as fish consumption advisories, provide insufficient protection to human health in the long term, and provide no protection to ecological resources. These principles are as true today as they were at the time of remedy selection. EPA should not rely on only partial controls on risk as justification for not performing any further necessary remedial work on this site.

I remain very concerned that EPA has abandoned its responsibilities under CERCLA to protect public health and the environment by failing to perform a complete Remedial Investigation for the portion of the site south of the Troy Dam. The Lower Hudson River is contaminated with PCBs from the Upper Hudson River throughout the entire Hudson River estuary south to New York Harbor. Human health and ecological risks associated with Lower Hudson River fish consumption are outside of EPA's acceptable risk range.

EPA has acknowledged in its May release of the proposed five-year review report that the remedial work conducted in the Upper Hudson River to date will not result in any significant reductions in public health and environmental risks. There is no longer any reason to delay the Lower Hudson River investigation and EPA should immediately ensure that it is undertaken.

I understand that EPA currently plans to end the public comment period on September 1. As noted above, DEC disagrees with EPA's current recommendation and finds that sufficient data exists to determine that the remedy is not protective. In addition, DEC believes that the data from the sampling we are currently conducting will further support this conclusion and will provide guidance on how to meet the goals of EPA's approved remedy. We will provide the results of this initiative this fall.

Enclosed to this letter is a set of general comments, and a set of more detailed technical comments on the proposed report and appendices. Please place this letter and attachments, my December 20, 2016 letter and attachments and any additional technical comments provided by staff, in the administrative record for this site. I look forward to receiving EPA's response to DEC's comments.

Sincerely,

Basil Seggos
Commissioner

Enclosure

NYSDEC General Comments on EPA's Proposed Hudson River Five Year Review Report

General Comment 1:

The Protectiveness Determination should be "Not Protective" for the river bottom remedy in the Hudson River between Hudson Falls and Troy (Operable Unit 2).

EPA's Five-Year Review guidance sets forth three critical questions that must be addressed for EPA to make a "Protectiveness" determination: (A) Is the remedy functioning as intended by the decision documents; (B) Are the exposure assumptions, toxicity data, cleanup levels, and remedial action objectives (RAOs) used at the time of the remedy selection still valid; and (C) Has any other information come to light that could call into question the protectiveness of the remedy?

The DEC document provided to EPA on December 20, 2016 combined with these comments shows that, after answering the three critical questions above, the only appropriate protectiveness determination for this Five Year Review is "Not Protective" for the river bottom remedy being implemented by EPA for the Hudson River PCBs site. The current level of human health and ecological risk throughout the entire site is in excess of EPA's acceptable risk range, including in the Upper Hudson, which is the fundamental metric that justifies this finding.

DEC provided a detailed rationale in our December 2016 document and it is not necessary to repeat it here. Data which has become available since December 2016 (the small sediment data set gathered by GE at EPA's direction in late 2016) and the 2016 fish PCB data, do not indicate that the current conditions in the Hudson River are protective. Rather, these data – particularly the fish data, which demonstrates fish PCB concentrations which give rise to human health and ecological risks above EPA's acceptable risk range - support DEC's primary contention that the current state of the Hudson River remedy for the contaminated sediments of the Upper Hudson is "Not Protective".

It is also important to point out that, given the current PCB concentrations in sport fish in the Upper Hudson, it is extremely unlikely that the fish PCB concentrations in the Upper Hudson will achieve the ROD targets for fish PCB recovery in the Upper Hudson, the first of which was to be met within five years after dredging was completed (2020). The most recent data (from 2016) indicate that the reach and species weighted average is 1.25 parts per million PCB. With the dredging completed in 2015, and the targeted concentration being 0.4 parts per million five years after dredging is completed, it will take fifteen years at the anticipated natural recovery rate of 8% per year to reach the first target. It would take natural recovery rates of over 20% to reach the first target in the five year time frame specified in the ROD, which is unrealistic and highly unlikely.

NYSDEC General Comments on EPA's Proposed Hudson River Five Year Review Report

General Comment 2:

EPA must follow its own guidance for issuing five year reviews and making protectiveness determinations. EPA's own guidance prevents EPA from issuing a "not yet protective but will be protective" determination after a remedy has been constructed.

The EPA Guidance on Five Year Reviews and Protectiveness Determinations (See Comprehensive Guidance on Five Year Reviews (EPA July 2001) and Clarifying the Use of the Protectiveness Determination (EPA September 2012)) describe in detail how EPA should conduct Five Year Reviews for all NPL sites across the nation. Nowhere in this guidance is it contemplated that a site which has a constructed remedy could receive a protectiveness determination of "not yet protective but will be protective". EPA is violating its own guidance by making up a new category of protectiveness which has never been employed or contemplated in the sixteen years that the Agency has had guidance on Five Year Reviews.

As noted above, EPA must also answer the question if any other information has come to light which would question the effectiveness of the remedy. EPA appears to be ignoring or downplaying all of the information which has become available after remedy selection that calls into question it's modelling and predictions, contrary to the Five Year Review guidance.

General Comment 3:

EPA appears to be abandoning the ROD targeted reductions in fish PCB concentrations that formed the basis for justifying the dredging remedy, and in doing so is arbitrarily ignoring critical questions A & B in its own Five Year Review guidance.

In the proposed five year review report, EPA is now stating that the remedy will not be protective until the ultimate remedial goal of 0.05 parts per million PCB in fish is reached. DEC urges EPA to enforce the selected remedy in the ROD and take the actions necessary to ensure that the remedy achieves the targeted rapid reductions in fish PCB levels, and thus human health and environmental risk, identified in the ROD. The ROD identified that the remedy would achieve the first target (0.4 parts per million or ppm PCB in average fish concentrations) within five years after dredging, and 0.2 ppm in sixteen years. This was the primary basis upon which EPA justified the dredging remedy, and the primary basis for the State's concurrence with the remedy.

EPA also identified these targets as representing, in EPA's view, points where there would be opportunity for the fish consumption advisories to be modified. However, EPA now appears to be pointing only to the ultimate remedial goal of 0.05 parts per million in fish, and no longer appears to be prepared to manage the remedy to achieve the ROD targets.

These ROD targets, representing rapid significant reductions in fish PCB concentrations and thus human health and environmental risk, were the primary basis used by EPA to justify the dredging remedy and the primary basis upon which the State concurred that the remedy would be protective of human health and the environment. EPA has provided no valid justification in its proposed report for abandoning these targets, other than being content to have a "wait and see" approach, while exposing the people and environment of New York State to unacceptable risks for many decades.

EPA should manage the remedy for this site so that the remedial targets identified in the ROD are achieved, and not focus solely on the ultimate remedial goal, which would only be achieved several generations into the future regardless of whether the remedial work was done or not.

General Comment 4:

EPA needs to follow the ROD and adaptively manage this remedial action, now in the "Monitored Natural Recovery" phase with dredging completed in 2015 and habitat reconstruction (planting) completed in 2016.

EPA should recognize that the remedy in the ROD represented EPA's best estimate as to how much remedial work would be necessary to meet the targets and goals set in the ROD. This estimate, based upon the tools available at the time, is what led EPA to determine the extent of remediation necessary for the rapid reductions in fish PCB concentrations, and thus human health and environmental risk, identified in the ROD.

At the present time, with the data from the project design and construction being available over the fifteen years since the ROD was issued, EPA now needs to update the site conceptual model, and gather the data necessary to determine if the amount of remedial work identified in the ROD will achieve the targeted reductions in human health and environmental risk.

DEC asserts that it is likely that further remedial work would be necessary to achieve the targeted reductions in fish PCB concentrations. More PCB was left behind than anticipated, and the most recent fish PCB concentrations indicate that it will likely take unrealistically high natural recovery rates to reach the targeted fish PCB concentrations, the first of which is to be reached five years after dredging.

In order for the remedy to be protective, the remedy should be managed to meet the targets set in the ROD. If the targets are not going to be met, then EPA should adjust the amount of remedial work done, not abandon the targets.

NYSDEC General Comments on EPA's Proposed Hudson River Five Year Review Report

General Comment 5:

EPA must update the agency's understanding of how the PCBs remaining in Hudson River sediments impact the water column and fish in the river.

There have been several important findings since the ROD was issued as it pertains the understanding of the distribution of PCB in Hudson River sediments, and how they impact water column and fish. EPA needs to update this understanding (called the "conceptual site model") to take these findings into account.

First, during the Sediment Sampling and Analysis Program (SSAP), the major data gathering program during project design (done mostly in 2002-2005), much more PCB mass in the river was found than previously thought, and much of this additional mass was closer to the surface.

Second, during implementation of the dredging program, it was again found that in certain areas of the river where woody debris had accumulated, there was significantly more PCB at depth than initially found in the SSAP, due to the debris preventing adequate sampling depth.

Third, the impact of the dredging work on the fish clearly shows that the increase in water column PCB concentration did not have a commensurate impact on the fish in the Hudson River. Typically, only those fish in the immediate vicinity of the dredging work, or immediately downstream, showed a significant reaction to the dredging. This indicates to DEC that the local sediments are much more important in controlling fish PCB concentrations than impacts from upstream sources, which in the Hudson River primarily means upstream sediments. This is most important for the Lower Hudson River, where the fish showed little to no response to the dredging work upstream, and it can no longer be expected that the remedial program in the Upper Hudson will result in significant improvement in fish PCB concentrations south of Albany.

EPA is again using overly optimistic model projections anticipating rates of natural recovery which are likely higher than what is happening in the river.

DEC raised this issue in a July 31, 2000 letter to EPA Region 2 during remedy selection, stating that this overly optimistic view of natural recovery rates (due to underrepresentation of the relative impacts of the sediments on fish) likely understated the benefits of active remediation. EPA understood that there was uncertainty in the modeling effort and, with that understanding, still set the targets in the ROD for protectiveness. EPA is again using the same model, which likely again underestimates the impacts of the local sediments on the fish, and is again likely underestimating the impact of the remaining contaminated sediments on the fish.

If EPA continues to use modeling for this site, as the ROD directs, then it will be necessary for EPA to restructure and recalibrate the model to reflect an updated conceptual site model which properly takes into account what has been learned since the ROD was issued. EPA has never given DEC or the public a valid scientific reason for not updating its modeling and flawed predictions.

General Comment 6:

EPA needs to develop and implement a monitoring plan which is designed to quantify the performance of the remedy at the temporal and spatial scale necessary to understand the remedy performance in a time frame commensurate with the time to reach the targeted rapid reductions in fish PCB concentrations.

DEC believes that the data gathering should be sufficient to understand, with the appropriate degree of statistical certainty, if the remedy is meeting the anticipated recovery rates in the time to reach the first target in year 2020.

To ensure statistical certainty, and to avoid missing differences in remedy performance in one area of the river as compared to another, the data gathering must be done on a spatial scale commensurate with the exposure driving the fish PCB concentrations. As the fish generally do not move between pools (the reaches of river separated by locks and dams), the fish will be impacted primarily by the sediments in the pool where they live. Sediments in Schuylerville will not drive PCB concentrations in fish at Waterford, some twenty-five miles downstream, and sediments in Waterford certainly will not drive PCB concentrations in Schuylerville. EPA's current approach would average between large reaches of river, restricting any ability to discern the actual performance of the remedy at the scale where the exposure occurs.

DEC has identified the data gathering which is necessary to understand the performance of the remedy, and urges EPA to follow the recommendations provided by DEC over a year ago.

General Comment 7:

Moving forward, DEC urges EPA to recognize that there is much more work to be accomplished to address the human health and ecological risk posed by the disposal of PCBs in the Hudson River. EPA should do the work necessary to ensure that the remedy in the Upper Hudson is protective, and to implement a full investigation and remedial program in the Lower Hudson south of Troy.

EPA should acknowledge that the remedy is currently not protective of human health or the environment, as the current risks are beyond EPA's acceptable range. EPA should collect the monitoring data necessary to quantitatively evaluate remedy performance as compared to the ROD targets, and to gather the data necessary to determine how to

modify the remedial work should the data indicate that the remedy will not or is not meeting the targets. In short, should the remedy not meet the targets, EPA should modify the remedy, not change the targets to make it appear to be protective.

EPA also should immediately exercise the authority to implement a comprehensive Remedial Investigation of the Lower Hudson River. The entire estuarine portion of the river south of the Troy Dam is contaminated with PCBs from the Upper Hudson, and EPA no longer expects the remedial program in the Upper Hudson to have much impact on the Lower Hudson River, particularly in the area south of Albany. In the meantime, EPA has no plans to move forward with an investigation of the distribution and impacts of the PCB contamination already present in the Lower Hudson transported from the Upper Hudson.

There is no reason to wait – this portion of the river is already part of the "National Priorities List" site. EPA already has the authority to issue an order to GE to implement a Remedial Investigation and Feasibility Study to determine the nature and extent of PCBs throughout the Lower Hudson, and to evaluate remedial actions needed to abate the human health and ecological risks that EPA currently recognizes as above the acceptable risk range.

Detailed Technical Comments - Attached

DEC has performed a detailed review of the document text and has evaluated the scientific information and assessments presented in the appendices. Attached to this letter is a list of detailed comments on the report. Please provide DEC with a written response to the issues raised in this letter and the attached comments, as well as to the written comments first provided in December 2016 and to the statements read at the public meeting and provided to EPA. DEC is, as always, prepared to meet with EPA to help advance the remedial program for the Hudson River and work toward our common goal of abating the human health and ecological risk caused by the disposal of PCB in the Hudson River.

NYSDEC's Detailed Comments – Five Year Review Report Text and Appendices

#	Report citation	Issue	Quote from document	Comment / Discussion	References
1	Executive Summary, page 1	Errata	"The purpose of this second five-year review (FYR) is to determine whether the remedial actions at the Hudson River PCBs Superfund Site (Site) are protective of public health and the environment and functioning as designed."	This is actually the third five year review for this site overall; the third for OU1, and second for OU2. The initial review of the remedy selected in the 1984 ROD was started in 1989 and culminated in the 2002 ROD for OU2.	
2	Executive Summary, page 2	Models	"Although these recent data present some encouraging results, further monitoring will be required to verify remedy effectiveness, but the analyses presented in this report demonstrate that the models used to support decision making were well-designed, remedial action objectives (RAOs) were appropriately developed, and remedy implementation is proceeding as planned."	USEPA states here that: (1) the models used in remedy selection were "well designed", (2) that the RAOs were "appropriately developed", and (3) remedy implementation is "proceeding as planned". This contradicts later statements that the model projections for reaching the interim targets can not be relied upon, and that the interim targets identified as RAOs should no longer apply.	
3	Executive Summary, Page 4	Reductions in Surface Sediment and Fish PCBs	"Available surface sediment data in conjunction with fish and water column concentrations indicate that surface sediment PCB concentrations are decreasing with time. The reduction in surface sediment concentration associated with dredging alone by river section was 87%, 36%, and 5% in River Sections 1, 2, and 3, respectively. Although the reduction associated with dredging in River Section 2 (RS2) was less than expected and may cause a lag in recovery, the overall surface sediment reduction is within ROD expectations."	EPA and DEC agree that there should be a close relationship between surface sediment PCB concentrations and fish PCB concentrations, particularly at a local level. In order to achieve the desired reductions in fish PCB concentrations, a commensurate reduction in sediment PCB concentrations must be achieved. The RAO interim targets for reach and species averaged fish PCB concentrations are to reach 0.4 ppm total PCB five years after dredging is completed. However, EPA's report states that only at 22% reduction in surface sediment PCB concentrations on a River Section length weighted average. As a result, it is unlikely that natural processes will be able to result in sufficient improvement to allow for surface sediments, and thus fish, to reach the ROD targets for reductions in PCB concentrations over time. The 2016 river section and species weighted average fish PCB concentration is, according to EPA, 1.25 ppm; it would take 25% reductions annually to reach 0.4 ppm by 2020, five years after dredging. At 8% per year (the model projected post dredging recovery rate), at the current fish PCB levels it would take 15 years to reach 0.4 ppm, and 23 years to reach 0.2 ppm. EPA would have had to achieve reductions due to dredging down to 0.6 ppm for an 8% improvement rate per year to reach 0.4 ppm five years after dredging. This equates to a reduction from 2.15 ppm (the 2004-	River Section 1 – 6 miles / 87% reduction River Section 2 – 6 miles / 36% reduction River Section 3 – 28 miles / 5% reduction [(6x0.87)+(6x0.36)+(28x0.05)]/40= 21.95% River Section Length Weighted Average reduction in surface sediment PCB concentrations

				2008 BMP mean) to 0.6 ppm, or a 72% reduction. It is not realistic to anticipate a 72% reduction in fish PCB concentrations with only at 22% reduction in surface sediment PCB concentrations.	
4	Executive Summary, Page 4	PCB mass reduction	Total PCB and Tri+ PCB mass removed were greater than planned, due to underestimates of the depth of contamination during the original remedial design. PCB mass in non-dredged areas is also greater than estimated in the 2002 ROD, although to a lesser extent than within the dredged areas. As calculated by EPA, the volume of sediment, mass of total PCBs, and mass of Tri+ PCBs removed during both Phases 1 and 2 were approximately 2,642,000 cubic yards of sediment, 155,800 kg of TPCBs, and 48,600 kg of Tri+ PCBs, respectively.	EPA here focuses on the amount of PCB removed; conditions in the river after dredging are not controlled by what was removed, but rather by what was left behind. EPA should not focus on the comparison of what was removed as compared to what was anticipated to be removed, as it is not relevant to the evaluation of whether or not the remedy is protective. Protectiveness is determined by evaluating the current site risks, and comparing them to the acceptable risk range. The current site risks are well above the acceptable risk range, and as a result the remedy is currently not protective. The amount of PCB left behind is much greater than anticipated, resulting (as EPA stated in 2012) a delay in reaching the remedial action objectives.	
5	Executive Summary, Page 4	Habitat reconstruction	Habitat replacement and reconstruction was conducted as anticipated. OM&M of restored habitat will continue until project objectives are met.	As discussed between DEC and EPA over the past several years, DEC believes that EPA has not required GE to perform sufficient habitat reconstruction to allow for the work to reach the habitat reconstruction goals. While not specifically relevant to the protectiveness determination, DEC will provide to EPA specific areas where further habitat reconstruction work is necessary to meet the habitat reconstruction goals.	
6	Executive Summary, Page 5	Model Forecast accuracy	Monitored natural attenuation is occurring and rates of decline are generally in agreement with the modeling done for the ROD:	EPA is overstating the actual observed rates of natural recovery which were ongoing at the time of remedy selection and design. "General agreement" is not a quantitative comparison; a more detailed quantitative analysis, taking into account the uncertainty associated with using different data sets over time, needs to be performed.	
7	Executive Summary, Page 5	Model Forecast accuracy - water	For the pre-dredging MNA period (1995-2008), water column Tri+ PCB concentrations declined at rates ranging from approximately 5 to 13 percent per year at the four Upper Hudson	Unfortunately, there are changes in stations, sampling methodology, and changes in flow regimes which complicate this analysis. EPA should properly account for these sources of	

			monitoring stations, and HUDTOX model simulations for this period were generally faithful to both seasonal and long-term trends.	variability and not rely upon the water data to support excessive rates of recovery in this document.	
8	Executive Summary, Page 5	Model Forecast accuracy - fish	Fish tissue concentrations declined during the pre-dredging MNA period (1995-2008). Rates of decline in the Upper Hudson for wet weight and lipid-normalized fish tissue PCB concentrations were approximately 12 to 20 percent per year and approximately 8 percent per year, respectively, consistent with rates estimated from the FISHRAND model output. Lower rates of decline were observed at locations farther downstream in the Lower Hudson River.	EPA should not be using the wet weight PCB data from the time period after 2005, as GE has admitted that their lab did not follow the acceptable and approved sample preparation protocol, introducing a significant negative bias and high variability to the wet weight PCB fish data. EPA knows this and should not have used this data in their understanding of site conditions. The lipid based PCB concentrations, while biased low for these years, is not biased to the degree as being unusable; however, data users should understand that the later BMP, and subsequent RAMP fish data (until 2015) are biased low. As a result, the estimates of natural recovery are biased high (overstating the rate of recovery) since the earlier data are without this bias, and the later data are biased low.	
9	Executive Summary, Page 5	Model Forecast accuracy - sediment	Available surface sediment data in conjunction with fish and water column concentrations indicate that surface sediment PCB concentrations are decreasing with time. Although the exact rate of decline is difficult to determine, as there is no single consistent sediment data set, the results using the available data indicate a decay rate similar to that predicted at the time of the ROD.	DEC has requested that EPA gather the sediment data necessary to quantify the change in surface sediment PCB concentrations over time at a scale (pool by pool) and in a time frame (commensurate with the remedial targets in the ROD) needed to evaluate remedy performance. EPA has thus far refused to do so, and as a result DEC has begun gathering the needed sediment data starting in Summer 2017.	
10	Executive Summary, Page 6	Monitoring recovery in fish PCB concentrations	2016 fish data suggest that fish have begun to recover from dredging impacts and are generally declining. It is important to recognize that up to 8 or more years of fish tissue data may be necessary to draw statistically based conclusions about trends, with a high degree of confidence, depending on the actual rate of decline that is experienced (it is anticipated that it will require approximately 8 years for fish tissue to decline to 50% of its current PCB concentration based on	It is not necessary to wait eight years to have the data necessary to determine if the fish PCB concentrations are reducing at a rate sufficient to achieve the remedial targets set in the ROD. All EPA needs to do is to perform the statistical power analysis, determine the number of fish samples to collect given the sample variance, and collect/analyze the appropriate number of fish. EPA has thus far refused to do so. Also, it is important that EPA points out here that the agency at the present time expects that it will take eight years for fish PCB concentrations to decline by half; with fish PCB concentrations (in reach and species weighted average fish) currently more than three times	

			an 8% decrease in lipid-normalized fish tissue concentration per year).	the ROD target of 0.4 ppm PCB, EPA could conclude today that the remedial target will likely not be met.	
11	Executive Summary, Page 6	Impact of remedy on the Lower Hudson	The rate of decline of fish tissue PCB concentrations generally decreases with distance downstream. As a result, there is a decrease in the correlation between fish PCB concentrations in the Upper Hudson River and Lower Hudson River with distance downstream. This indicates that PCB sources in the Upper Hudson River have less of an impact on Lower Hudson River fish than on fish in the Upper Hudson.	DEC agrees that the remedy in the upper Hudson is not likely to have a significant impact on fish in the lower Hudson. EPA needs to clarify this statement, however, to point out that the GE sources in the upper Hudson are the primary source of PCBs in the Lower Hudson, and that presently GEs PCBs currently still coming out of the upper Hudson are much less of a source to lower river fish that GE's PCBs already in the Lower Hudson as a result of past discharges. EPA should not state that PCB sources other than GEs discharges in the upper Hudson are controlling lower Hudson fish PCB concentrations unless the agency has data to support such a conclusion.	
12	Executive Summary, Page 6	Impact of construction schedule on recovery rates	Overall, the project has been implemented as anticipated in the ROD. Dredging activities did include several operational differences from assumptions in the ROD with potential impacts on recovery rates in fish. Some of these differences included a delayed start to dredging, significantly increased mass removal, the use of a single processing facility, and dredging in multiple river sections simultaneously.	DEC agrees that there may be a delay in the start of recovery based upon construction schedule. However, this delay would only be one to two years at worst, in the landlocked reach in River Section 2 between the Fort Miller Dam and the Thompson Island Dam. There should be little or no delay in the Thompson Island Pool, as there was little remedial work in this River Section over the last two years of the remedy. Similarly, there should be no delay in River Section 3, as these reaches of river were dredged in a sequence nearly identical to that planned. ALSO, there should be no impact whatsoever on the post dredging recovery rates caused by the schedule of the work; in all cases, the post dredging recovery rates are and were assumed to be driven by the post dredging natural recovery processes which are not impacted by construction schedule. It is also important to point out that EPA, in the ROD, already built in a two year delay; while the model predicted reaching 0.4 in three years, the ROD says "within five".	Also - in RS1, the water quality data during the last few years of dredging showed little or no impact from dredging operations; the data were often non-detect for PCBs. The dredging work in the last year of the project were well downstream of the fish sampling locations (just above the TI Dam), or of short duration (two weeks) at the very northern end of the pool.
13	Executive Summary, Page 7	Health Risk Assessments	For OU2 (in-river sediments), the risks that were calculated for the ROD were re-assessed using current exposure assumptions, toxicity values, and standards to determine if the conclusions of the risk assessment or the protectiveness of the remedy has changed. Although there have been	EPA here makes one of the State's main points; the human health risk associated with this site is still well above the acceptable risk range, the conclusions reached in both the upper Hudson and lower Hudson human Health Risk Assessments done during the Reassessment RI/FS.	

			some updates to the exposure assumptions used in the human health risk, the updates do not change the conclusions of the risk assessment. Toxicity values for human health were taken from the Integrated Risk Information System for both cancer and non-cancer health effects, consistent with EPA guidance. EPA determined that the human health RAOs developed in the 2002 ROD are still valid and appropriate for the Site.		
14	Executive Summary, Page 7	Ecological Risk Assessment	For ecological risk, there were some changes to exposure parameters (some increasing and some decreasing) and toxicity values (i.e., the Lowest Observed Adverse Effect Level (LOAEL) and No Observed Adverse Effect Level (NOAEL)). Overall, use of these updated values would result in calculated risk ranges that are narrower than presented in the ROD, with a slight reduction in the upper bounds of the risk-based concentration ranges for PCBs in fish consumed by river otter and mink. This refinement results in risk-based ranges that reduce uncertainty and focus the range of PCBs in fish expected to be protective of the ecological exposure pathway. The lower bounds of the updated ranges are not lower than the lower bounds for both ranges identified in the ROD, and the refinements of toxicity values and exposure parameters do not affect the protectiveness determination of the selected remedy.	As with the human health risk assessments, EPA here makes one of the State's main points; the ecological risk associated with this site is still well above the acceptable risk range, the conclusions reached in the Ecological Risk Assessments done during the Reassessment RI/FS.	
15	Executive Summary, Page 8	Protectiveness Statement for OU2	OU2: Based on data collected and reviewed to date, EPA expects that the remedy at OU2 will be protective of human health and the environment upon completion. Remedial activities completed to date have substantially reduced PCB source materials in the Upper	The State disagrees with the protectiveness determination. The remedy is not protective if it will be several decades until PCB concentrations in fish will no longer require that the State recommend that human consumption of fish be limited, and until significant ecological risk has abated. The State also believes that EPA should recognize and articulate in the Five	

			Hudson River. As expected in the Record of Decision, average PCB concentrations in fish in the Upper Hudson are declining but have not yet reached protective levels. Therefore, as of the date of this five-year review, EPA recognizes the remedy at OU2 to be not yet protective of human health and the environment. Because the remedy includes not only the dredging component but also the subsequent period of monitored natural attenuation, EPA will not consider the OU2 remedy to be complete until the natural attenuation component also has been completed. Based on all the available data to date, EPA expects that continued natural attenuation following the completion of dredging will achieve the long-term remediation goal for the protection of human health with regard to fish consumption (0.05 mg/kg PCBs in species-weighted fish fillet). As EPA indicated in the Record of Decision, EPA believes it likely that improvement will occur gradually over several decades at least. In the interim, the State of New York has in place fishing restrictions and advisories against consumption of fish to control human exposure pathways that could result in unacceptable risks. EPA acknowledged in the 2002 ROD that the consumption advisories are not fully effective in that they rely on voluntary compliance in order to prevent or limit fish consumption. EPA will continue to work with New York State to ensure the ongoing maximum effectiveness of the advisories.	Year Review Report that there are currently, and will be for decades into the future, uncontrolled human health and ecological risk. EPA should also recognize and articulate in the Five Year Review Report that the fishing restrictions and consumption advisories are only partly effective in limiting human fish consumption, and are of no effect to address ecological risk.	
16	History of Contamination,	Reference to PCB mass discharges	From approximately 1947 to 1977, GE discharged an estimated 1.3 million pounds of PCBs into the Hudson River from its capacitor	Although this estimate of mass discharged to the river by GE from the capacitor plants in Hudson Falls and Fort Edward has been repeated many times, by many parties (including DEC) in	

	section 1.1.5, page 12		manufacturing plants at Hudson Falls and Fort Edward.	the past, DEC has concluded recently that there is no basis in the record for this estimate. DEC now believes that it is inaccurate and inappropriate to continue to cite this estimate. The actual mass discharged to the river is unknown, and may be much more than 1.3 million pounds (650 tons).	
17	Five Year Review Summary Form, page 14	Construction completion status	The form here states "No" in response to "Has the site achieved construction completion?"	Dredging was completed in late 2015. Habitat reconstruction as per the scope of work was reportedly completed in 2016. Facility decommissioning work was completed in late 2016. Construction is complete.	
18	Five Year Review Summary Form, page 14	Review Number	The form here states "2" in response to "Review Number".	This is actually the third five year review for this site overall; the third for OU1, and second for OU2. The initial review of the remedy selected in the 1984 ROD was started in 1989 and culminated in the 2002 ROD for OU2.	
19	Remedial Action Objectives (RAOs), pages 17-18	Identification of remedial action objectives	"Reduce the cancer risks and non-cancer health hazards for people eating fish from the Hudson River by reducing the concentration of PCBs in fish. The risk-based preliminary remediation goal (PRG) for the protection of human health is 0.05 mg/kg PCBs in fish fillet based on non-cancer hazard indices for the RME adult fish consumption rate of one half-pound meal per week (this level is protective of cancer risks as well). Other target concentrations are 0.2 mg/kg PCBs in fish fillet, which is protective at a fish consumption rate of one half-pound meal per month and 0.4 mg/kg PCBs in fish fillet, which is protective of the CT or average angler, who consumes one half-pound meal every two months. Attaining such levels might facilitate the relaxation of the fish consumption advisories and fishing restrictions (e.g., the "eat none" advisory for the Upper Hudson could be relaxed as conditions improve)." (AND) "In the	This is the portion of the ROD text where EPA specifically identifies the target concentrations in the ROD as remedial action objectives. In the ROD, EPA also states that "*The time to reach target PCB concentrations in fish was a primary factor in comparing remedial alternatives. As more fully described in Section 11.1 - Overall Protection of Human Health and the Environment, the time to reach target levels (e.g., 0.2 and 0.4 mg/kg) favors the active remediation alternatives.*" (ROD, pages 66-67)	See also ROD pages 71-72, Section 11.1; EPA relies upon the time to reach the 0.4 and 0.2 targets to differentiate between the alternatives and justify the selected remedy.

			ROD, EPA adopted the preliminary remediation goals identified above as the remediation goals for the Site."		
20	Institutional Controls, page 22	Effectiveness of Controls	"It is noted that the fish advisories rely on voluntary compliance and therefore are not completely effective in preventing fish consumption."	This understanding is a primary basis for the need, identified in the ROD, for rapid reductions in human health risk in the years immediately following remediation.	See also ROD page 104: "*Institutional controls do not protect ecological receptors, and human health risk reduction relies on knowledge of and voluntary compliance with the consumption advisories and fishing restrictions. Consequently, the active remedial alternatives are substantially more protective of people who do not follow the fish consumption advisories, because of the residual risk in consuming fish and the shorter time required to reach fish PCB target levels under those alternatives.*"
21	Operation and Maintenance, page 22	Scope of OMM	"EPA is currently considering whether any modifications are necessary to the OM&M programs identified in the Phase 2 OM&M Scope, which is an attachment to the consent decree under which GE is implementing the OU2 remedy."	DEC has already provided to EPA, by emails on February 10 and May 18, 2016, and by letter on March 10, specific recommendations on the needed scope of monitoring to evaluate remedy performance for this site. DEC also provided specific thoughts on the scope of sediment sampling by letter on November 14, 2016, when chose to approve a limited sampling effort for sediments in the upper Hudson.	
22	Operation and Maintenance, page 22	Scope of OMM	"The work plan for sediment sampling under OM&M was completed October 2016 in part to get the sediment samples collected as soon as possible post-dredging since it takes long periods of time (5 years) between sample events to properly measure changes in concentration."	EPA is incorrect in stating that long periods of time are necessary to properly measure changes in concentrations. EPA can make the appropriate evaluations to measure changes in concentration by using standard power analyses to determine the numbers of samples needed for the desired statistical power. In other words, EPA need only collect more samples to decrease the time needed to understand the changes in PCB concentrations over time.	

23	Technical Assessment, Section 5.1, pages 30-31	Analytical Bias in Fish Data due to Failure to Follow Proper Sample Preparation Protocols	"However, from 2007 to 2013 the GE fillet samples were processed while excluding the ribs of the fillet (*i.e.,* "rib-out" fillets), which is not consistent with New York State protocols. For this period, time trend analyses of PCB levels in fish fillets on a wet weight basis do not include these data, although the data are displayed in the various graphs of the report. The "rib-out" issue does not apply to whole body trend analysis (typically performed on fish collected in the fall) and does not affect lipid-normalized fillet trend analyses."	The failure of GE's contractor to follow the proper sample preparation protocols does impact the lipid normalized trend analyses. There is a downward bias in the lipid normalized PCB data on the order of 15%. EPA has determined that this is not significant; however, analyses of the data from the period 2007 to 2013 should include the understanding that the LPCB data from the GE lab is biased low.	
24	Technical Assessment, Section 5.1, page 31	Interpretation of Fish PCB data	"Dredging was completed in 2015 and, thus, the most recent data available (collected in 2016) reflect conditions less than a year after completion of dredging and that were still influenced by dredging-related impacts."	The 2016 spring sport fish in the upper Hudson (black bass, bullhead, perch) should be assessed as being impacted by the dredging work which ended in 2015, as the trend in fish PCB data indicates that the spring fish represent the previous years' conditions. The fall 2016 forage fish, however, should indicate the first year of post dredging conditions, as they went through an entire growth season in 2016 without dredging impacts.	
25	Technical Assessment, Section 5.1, page 31	Rationale for EPA's abandoning the targeted fish PCB concentrations identified in the ROD.	"Further monitoring will be required to verify remedy effectiveness, but the analyses presented in this report demonstrate that the models used to support decision making were well-designed, RAOs were appropriately developed, and remedy implementation is proceeding as planned. The project is currently transitioning from remedial action to the OM&M phase."	If the models used to support decision making were well-designed, the RAOs appropriately developed, and remedy implementation proceeded as planned, then why is EPA no longer seeking to reach the 0.4 ppm and 0.2 ppm fish PCB targets in the ROD?	
26	Technical Assessment, Section 5.1, page 31	PCB remaining in un-dredged areas in the Upper Hudson	"It is recognized that PCB mass in non-dredged areas is also greater than originally estimated, although not to the same extent as within the dredge areas."	EPA has not yet made a quantitative assessment of the PCB mass remaining in non-dredged areas as compared to previous estimates. This assessment is important in understanding long term performance of the remedy.	

27	Technical Assessment, Section 5.1, page 31	Reduction in surface sediment PCB concentrations	"The overall reduction in surface sediment Tri+ PCB concentrations in the three river sections as a result of dredging was 87%, 36%, and 5% in River Sections 1, 2, and 3, respectively. Although the reduction associated with dredging in River Section 2 was less than expected and may cause a lag in recovery, the overall surface sediment reduction in PCB levels is within ROD expectations."	According to EPA's previous five year review report (Appendix A, Table 1 - the EPA prediction from the model, used for the ROD), the reduction anticipated in the ROD was 79% for River Section 1, 64% for River Section 2, and 4.4% for River Section 3. Clearly, the reductions in River Section 2 were not within expectations. This Appendix also states that a delay of ten years in fish PCB recovery should be expected in River Section 2 as a result of this increase in remaining PCBs over what was anticipated.	
28	Technical Assessment, Section 5.1, page 32	Habitat reconstruction	Habitat reconstruction and replacement was conducted as anticipated to mitigate impacts from the dredging operations. OM&M of reconstructed habitats will continue until project metrics are met.	There are significant problems with the habitat reconstruction effort. DEC has provided to EPA, on multiple occasions, detailed comments on the need for further habitat reconstruction work to facilitate recovery of impacted habitats.	
29	Technical Assessment, Section 5.1, page 33	Sediment Recovery Rates	EPA has estimated an annual natural recovery rate of approximately 5 percent for surface sediment	If EPA believes that the sediment recovery rate is 5% on an annual basis, then the agency should also conclude that the fish recovery rate will also be ~ 5%.	
30	Technical Assessment, Section 5.1, page 33	Fish Recovery Rates	2016 fish data suggest that fish have begun to recover from dredging impacts and are generally back to pre-dredging levels. The average PCB concentration in Upper Hudson River fish at the time of the 2002 ROD was approximately 3 mg/kg (species-weighted, wet weight); prior to the start of dredging in 2009 the species-weighted, wet weight average was 1.4 mg/kg; in 2016 the average was 1.3 mg/kg.	The river section and species weighted average fish PCB concentration is here stated to be 1.3 ppm (mg/kg). At 5% annual recover rates (in keeping with the sediment recovery rate above) it will be 24 years until the 0.4 ppm target is reached, and 38 years until the 0.2 ppm target is reached. These were stated in the ROD to be reached in 5 and 16 years after dredging.	
31	Technical Assessment, Section 5.1, page 33	Fish Recovery Rates	It is recognized that up to 8 or more years of fish tissue data may be necessary to draw statistically valid conclusions about trends.	EPA can draw statistically valid conclusions about trends simply by gathering more samples per year.	

32	Technical Assessment, Section 5.1, page 33	Purpose of OMM program	Monitoring of water, fish, and sediment will continue under the OM&M program to confirm that natural attenuation continues to occur and the remedy is functioning as intended.	If the purpose of the OMM monitoring of water, sediment and fish is to confirm that natural attenuation continues to occur, and that the remedy is functioning as intended, then the sampling program must be designed to answer those questions. The remedy was intended to meet 0.4 ppm in reach and species weighted fish within five years; the water, sediment and fish monitoring must therefore be designed to answer the question "Will the reach and species weighted average fish PCB concentrations reach 0.4 ppm within five years after dredging?" The environmental medium in which the attenuation is to occur naturally is surface sediments; therefore the monitoring program must be designed to answer the question "Is the attenuation of PCB concentrations in surface sediments occurring at the rates necessary for the fish to reach 0.4 ppm within five years after dredging?"	
33	Technical Assessment, Section 5.1, page 33	Lower River	Limited data collection from the lower river indicates that recovery rates are slower than in the Upper Hudson River and may not be strongly associated with PCB loading from the Upper Hudson River.	EPA here admits that conditions in the Hudson River are such that a full investigation is needed in the lower River to understand how GE's PCBs already in the sediments of the lower Hudson are controlling water column and fish PCB concentrations, and to determine what remedial actions may be necessary to address the human health and ecological risks in the lower Hudson posed by the sediment PCBs.	
34	Technical Assessment, Section 5.1, page 33-34	Impact of Schedule on Remedy	Overall, the project has been implemented as anticipated in the ROD. The project implementation did include several operational differences from assumptions in the ROD with potential impacts on recovery rates in fish. Some of these differences included a delayed start to dredging, significantly increased mass removal, the use of a single processing facility, and dredging in multiple river sections simultaneously.	EPA, in Appendix 8, describes how there may be an up to two-year impact on recovery rates associated with construction sequencing and the apparent lack of consideration of construction impacts in the model predictions. However, (as EPA now states) EPA anticipated reaching the 0.4 ppm targeted fish PCB concentration two years after dredging, and the ROD text said up to five years to reach the 0.4 ppm target, there is no need to adjust expectations based upon this issue...EPA already took in into account at the time of the ROD, in making the time to target five years instead of two.	

35	Project Operated and Functioned as Designed, Section 5.1.1.2, p. 36	Purpose of OMM program	The OM&M sediment sampling program, specifically designed to monitor long-term changes in sediment PCB concentrations, will produce the most comprehensive sediment dataset to evaluate PCB concentration trends in Upper Hudson River sediments. As there are no RAOs or remediation goals specifically linked to sediment PCB concentrations, the OM&M sampling is intended to create a diagnostic dataset to better understand recovery from dredging-induced disturbances in the Upper Hudson River, but not as a direct means to determine whether (nor where) further remediation of the Upper Hudson River may be warranted.	EPA here misstates the purpose of gathering the sediment data during OMM. According to the OMM Scope document, the objectives are (see section2.3.1) (1) Determine post-remediation PCB levels in sediments in non-dredge areas of the Upper Hudson River; (2) Provide data on Select Areas that exceeded the MPA removal criteria that were not targeted for removal because they were buried by cleaner sediments to assess whether the deposits have experienced erosion; (3) Determine sediment recovery rates in non-dredge areas of the Upper Hudson River; and (4) Examine the changes to surface PCB concentrations in backfill areas. EPA needs to design and implement a sediment sampling program to be used in OMM which meet the overall goal for the OMM program which is to "provide data on PCB levels over time to assess whether the Remedial Action Objectives (RAOs) and Remediation Goals (RGs) set forth in the ROD are being achieved." EPA must focus monitoring effort toward assessing progress toward reaching the near term objectives, and not just on long term changes.	
36	Project Operated and Functioned as Designed, Section 5.1.1.2, p. 37	Basis for Five Year Review analysis of remedy function	For this five-year review, the following criteria represent the primary metrics for evaluation of remedy function: (1) Baseline trends and construction impacts (Water column PCB concentrations prior to and during Phase 1 and Phase 2 dredging (refer to Section 5.1.1.3.3) and fish tissue PCB concentrations prior to and during Phase 1 and Phase 2 dredging (refer to Section 5.1.1.3.4); (2) Sediment and PCB mass removal via Phase 1 and Phase 2 dredging (refer to Section 5.1.1.3.2); (3) Pre-dredging MNA period trends (refer to Section 5.1.1.3.5) and (4) Capping Effectiveness (refer to Section 5.1.1.4).	This passage summarizes the primary problem with the rationale used by EPA to support a protective determination other than the appropriate "not protective". Here EPA states that the evaluation of how the dredging remedy is performing on conditions before the remedy was implemented, and during implementation. The conditions before and during dredging did not, do not, and will not control the rates of decline in fish, water and sediment PCB concentrations. EPA should not use these data from before and during dredging to quantify the rates of improvement after dredging due to natural recovery.	

37	Evaluation of PCB Mass Removal, Section 5.1.1.2.1, p. 39-41	Detailed Evaluation of PCB Mass Removed	(This entire section focuses on the percentage of PCB mass removed within the upper Hudson River)	EPA misses the point. The ability of natural recovery to achieve the recovery in surface sediment PCB concentrations needed to meet EPA's remedial goals is driven by how much PCB was left behind, not on how much was removed.	
38	Habitat Reconstruction, Section 5.1.1.2.3, p. 43-44	Loss of Habitat due to Remedy	(This entire section focuses on the reconstruction of habitat in the project area)	DEC believes that substantial unnecessary habitat loss occurred during the remedial work due to the failure of EPA to follow applicable State guidance and law.	
39	PCB Levels in Fish, Sediment and Water are Declining, Section 5.1.1.3, p. 44	Post Dredging Recovery	The length of time needed to achieve remedial goals and remedial action objectives was an important factor considered by EPA in the 2002 ROD.	EPA should continue to manage this site as though the time to reach remedial goals continues to be important. However, EPA has chosen to ignore the interim targets and instead focus on the long term goal, which would be achieved in about the same time whether or not the dredging occurred. EPA needs to manage this site to meet the ROD interim targets upon which the remedial decision were based - achieving 0.4 ppm in reach and species averaged fish five years after dredging, and achieving 0.2 ppm 16 years after dredging.	
40	PCB Levels in Fish, Sediment and Water are Declining, Section 5.1.1.3, p. 44	Post Dredging Recovery	The HUDTOX model computed an effective rate of decay in sediment concentrations of approximately 8 percent per year for the calibration period. Consistent with the close relationships among sediment, water, and fish tissue PCB concentrations, FISHRAND generated rates of decline of PCBs in fish tissue similar to rates observed in HUDTOX over the 1977-1998 time period, as discussed in Appendix 3. Following dredging, the models predicted continued declines in tissue concentrations, although the upstream project boundary PCB load ultimately results in asymptotic non-zero PCB concentrations in fish (see, e.g., 2002 ROD, p. 54).	EPA here states a fundamental assumption made in selecting remedy - the removal of the sediment targeted in the ROD would result in a post dredging recovery rate of 8% per year, which, because sediment and fish PCB concentration are closely related, would result in post dredging recovery rates of 8% in both media. If this is not being achieved, then EPA should adjust the amount of sediment removed.	

41	PCB Levels in Fish, Sediment and Water are Declining, Section 5.1.1.3, p. 44-45	Post Dredging Recovery	In addition, EPA considered a target concentration of 0.2 ppm PCBs (wet weight) in fillet based on one half-pound meal per month, and a target concentration of 0.4 ppm based on the average (central tendency) consumption rate of one half-pound meal every 2 months. The target concentrations (which can be considered interim milestones) correspond to points at which the fish consumption advisories could be relaxed from the current "eat none" recommendation in the Upper Hudson River to allow a limited number of fish meals (*i.e.,* ranging from 6 to 12) per year, as recovery of the river progresses to the point where unlimited consumption is safe. It should be noted that the fish consumption advisories are under the control of NYSDOH.	EPA here confirms the importance of the 0.4/0.2 ppm targeted (reach and species average) fish PCB concentrations, noting the importance of reaching PCB levels which correspond, in EPA's view, to levels representing reduced human health risk allowing consumption.	
42	PCB Levels in Fish, Sediment and Water are Declining, Section 5.1.1.3, p. 45	Post Dredging Recovery	Modeling presented as species-weighted averages in Table 11-2 of the ROD showed that neither MNA nor the selected remedy would achieve the human health remediation goal of 0.05 ppm PCBs for RS1, RS2, or for the Upper Hudson River as a whole, within the modeling time frame (to 2067) unless the upstream source was virtually eliminated, but would be achieved within 40 years in RS3 (RM168-154).	Here EPA confirms the critical importance of the interim targets, which provided the basis for selecting the dredging remedy. There is no difference between any of the alternatives in reaching the long term target of 0.05 ppm total PCB; the only difference was the time to reach the interim targets (the dredging remedy provided significant rapid risk reductions compared to not dredging).	
43	PCB Levels in Fish, Sediment and Water are Declining, Section 5.1.1.3, p. 45	Post Dredging Recovery	The model results averaged over three species in the entire Upper Hudson River, as presented in Table 11-2 of the ROD, project that a target level of 0.4 mg/kg wet weight could be achieved several years after completing dredging and after 15 years for the 0.2 mg/kg wet weight target level.	The ROD text actually says five and sixteen years, respectively, to reach the 0.4 and 0.2 ppm reach and species weighted average concentration.	
44	PCB Levels in Fish, Sediment and Water	Post Dredging Recovery	The median largemouth bass concentration of PCBs is close to the 0.4 mg/kg target level, and	Here EPA is "comparing apples and oranges." The median is different than the average (also known as mean). Given the	

	are Declining, Section 5.1.1.3, p. 45		the yellow perch median is below this target level. Similarly, Figures A3-3 and A3-4 show that in RS2 (RM184) and RS3 (RM154-168), largemouth bass median tissue concentrations are close to 0.4 mg/kg and median yellow perch levels have achieved the 0.4 mg/kg target concentration.	distribution of the fish PCB data, the median is less than the mean. EPA in discussing the interim targets which were AVERAGES, should not be presenting data in terms of MEDIANS, which are not the same thing. It is also important to point out that the targeted concentrations in the ROD were species weighted as well as river section length weighted, meaning that the comparisons to individual species at individual locations are not particularly meaningful when comparing to the metric EPA chose in the ROD. DEC does agree, however, that comparisons at specific locations are very important in understanding remedy performance over time, and encourages EPA to gather fish, sediment, and water data on a pool by pool basis rather than river section basis.	
45	PCB Levels in Fish, Sediment and Water are Declining, Section 5.1.1.3, p. 46	Post Dredging Recovery	As also discussed earlier, actual dredging activities deviated from the upstream-to-downstream pattern of dredging anticipated at the time of the ROD. For example, dredging occurred in RS1, the most upstream river section, during the final year of the remedy. As a result of this and other operational modifications (described in Appendix 8), specific predictions of dredging-related impacts to water column, sediment, and fish tissue concentrations as presented in the ROD differed in some respects from what was observed. Appendix 8 also discusses short term impacts to fish tissue concentrations as a result of these modifications. As expected, these impacts were spatially and temporally transient.	The work in River Section 1 in the last year of dredging, with the exception of a small area for a few weeks near Rogers Island, was all at the extreme south end of the pool, well downstream of the five fish sampling locations in this pool. This work would not have had a significant effect on the fish PCB concentrations gathered in River Section 1 in either the spring or the fall of 2015 or 2016.	
46	PCB Levels in Fish, Sediment and Water are Declining, Section 5.1.1.3, p. 46	Post Dredging Recovery	Less than one year of post-dredging data is available, and additional years of monitoring data are required for a robust statistical evaluation of post-dredging MNA trends. This five-year review assesses the current status of the river	This statement contradicts much of the report, which relies on the use of pre-dredging data to support the effectiveness of the modeling effort to support the use of the model to predict success of the remedy. A true assessment of the post remedy fish data suggests that it is very unlikely that the ROD targeted	

			using the most current post-dredging data for sediment, water column and fish tissue PCB concentrations, and provides preliminary indications of system response to implementation of the remedy.	rapid reductions in fish PCB concentrations, which formed the primary basis for selecting and implementing the remedy, will not be achieved in the time frames identified in the ROD.	
47	Page 61	Consumption Advisories	"…commercial fisherman…"	Replace with "…fisherman's associations…"	
48	Page 62	Consumption Advisories	"According to NYSDOH, since 2011 certain communities in the Lower Hudson Region (south of Bear Mountain Bridge) may ***have been*** less aware…"	Replace with "According to NYSDOH, previous consumption surveys indicate that certain communities in the Lower Hudson Region (south of Bear Mountain Bridge) may be less aware…"	
49	Page 62	Consumption Advisories	"Therefore, according to NYSDOH, in 2011 NYSDOH ***began focusing more of*** its outreach efforts on the Lower Hudson River Region and since 2012, to more recently observed demographic groups."	Replace with "Therefore, according to NYSDOH, in 2011 NYSDOH continued its outreach efforts in the Lower Hudson River Region and since 2012, to more recently observed demographic groups."	
A4-1	Appendix 4 - General Comment	Surface Sediment Concentrations	(General Comment)	It is important to point out that in Appendix 4, EPA is making a fundamental error - assuming that all of the changes in sediment PCB concentrations are the result of natural recovery. Since 1977, there have been a number of significant events which impact sediment PCB concentrations which are not the result of natural processes. Assuming that changes in sediment PCB concentrations are the result of natural processes (only once in Appendix 4 is source control even mentioned as a potential factor in changes of sediment PCB concentrations) fundamentally confounds the use of Appendix 4 as a source of understanding the rates of natural recovery. For example, looking at rates of recovery between 1977 and 1991, without taking in to account the impact of the cessation of PCB discharges to the Hudson in 1977, remedial measures at the remnant sites, and initial abatement measures at the GE plant sites, significantly overestimates the rates of improvement due to "natural recovery" during this time period. Similarly, the reduction in PCB sources to the river due to numerous remedial	

				measures taken at the GE plant sites over many years starting in the late 1980s at Fort Edward in the early 1990s at Hudson Falls, throughout the period leading up to the start of dredging in 2009 similarly confounds the use of the sediment data to understand rates of "natural recovery". Without taking the impact of source control into account, all of EPA's estimates of rates of natural recovery represent overestimations and upper bounds; recovery rates could be no higher, but the recovery due to natural processes are very likely much less, as the impacts of source control likely dominated changes to the system during the periods in question.	
A4-2	Appendix 4, page 1-1	Sediment - Fish relationship	The reduction in fish tissue PCB concentrations that will be achieved by the overall reduction in the PCB mass that may become bioavailable is closely related to the surface sediment PCB concentration throughout the Upper Hudson. In the selected remedy, reduction of PCBs in surface sediment is achieved through two important processes: 1) sediment removal by dredging and backfilling, and 2) monitored natural attenuation (MNA). Both processes are required to achieve the goals of the ROD. In general, fish body burdens are expected to track with the changes in surface sediment PCB concentrations (*i.e.*, if residues decrease in the surface sediment, then they should also decrease in the overlying water column, and with reductions in sediment and water, the residues in fish should decline as well). Bioaccumulation relationships are site-specific, and in any given setting, if a 10- fold reduction in fish body burden is targeted, then, at a minimum, a 10-fold reduction must be achieved in the media to which fish are exposed (sediments and overlying water).	There is no reason to believe that the sediment - water - fish relationship is different from one reach of the upper Hudson to another. EPA can not have it both ways - either the local surface sediments drive fish PCB concentration, or they do not. EPA has no basis to suggest that the sediments in River Sections 1 and 2 control fish PCB concentrations, while the water column controls fish PCB concentrations in River Section 3. The fish and water PCB data gathered during implementation of the remedy indicate that there could be large increases in water PCB concentrations without corresponding increases in fish PCB concentrations, indicating that the surface sediment PCB concentrations are much more significant contributors to fish PCB than water column PCBs at this site. Local sediments drive local fish. In order to achieve reductions in fish PCB concentrations, reduction in local surface sediment PCB concentrations are likely necessary.	

			This may be achieved directly by reducing contaminant concentrations in sediments composing the feeding/home range of the fish, or as in River Section (RS) 3, indirectly by reducing water column concentrations impacting prey downstream of sediment remediation areas.		
A4-3	Appendix 4, page 2-1	Usability of past sediment sampling programs for temporal analysis	Sediment data are inherently spatially limited, and are typically obtained from samples collected using a coring device or a grab sampler. In trying to characterize large areas of the river bottom, care must be taken to obtain spatially representative samples. Because of the highly variable nature of PCB sediment concentrations, even over short distances (less than 2 meters), a statistically appropriate number of samples and an appropriate sample design are needed to accurately measure the mean concentration in a given area. Thus, any program to monitor temporal changes in surface sediments must be designed accordingly and, in addition, multiple sample rounds need to be collected over time in a consistent way. None of the sediment sampling programs conducted to date was designed specifically with this objective (*i.e.,* to represent changes in sediment PCB concentrations over time), with the exception of the 2016 data collection. As a result, conclusions about concentration trends should be drawn cautiously and their limitations clearly discussed.	DEC agrees; none of the past sediment sampling programs were designed and implemented in a manner which allows for meaningful quantitative temporal analysis of trends in surface sediment PCB concentrations. EPA had an opportunity to implement such a program, designed to achieve the needed data quality objectives - to determine if the post dredging improvement in surface sediment concentrations due to natural recovery is occurring at the rate necessary to achieve the ROD objectives. This is why DEC undertook a sediment sampling program in 2017 to answer this essential question. EPA's sediment sampling program, due to insufficient number of samples, will not answer this question until several years after the first ROD targets are to be reached.	
A4-4	Appendix 4, page 2-1	Usability of past sediment sampling programs for temporal analysis	(See above)	It is also important to point out that EPA here clearly describes the limitations of the analyses presented in Appendix 4. DEC views these analyses as informative, but not quantitative with the degree of certainty needed to evaluate the rate of recovery prior to dredging. It is also an error to try to anticipate or	

				estimate the rate of post-remedial recovery in surface sediment concentrations based upon the rate of improvement before the remedy, as there has been fundamental changes in the system due to source control before dredging and sediment removal/backfilling as part of the dredging.	
A4-5	Appendix 4, page 2-8	2016 Sediment sampling	GE's 2016 surface sediment sampling program was designed under EPA direction as part of the OM&M sediment monitoring program to assess long-term recovery following the completion of the dredging remediation via the collection and analysis of surface sediment samples from both non-dredged and dredged areas in the Upper Hudson River. The 2016 sampling event establishes the initial year of the required sampling design in non-dredged areas. The required sampling of the dredged areas will occur in 2017. Determination of the required number of samples and their locations was based on EPA's sampling design analysis.	EPA should reveal here the fundamental basis for the sample design analysis - understanding the rate of change over ten years, on a river section by river section average basis, which is not sufficient to understand the performance of the remedy in a time frame commensurate with the remedial targets.	
A4-6	Appendix 4, page 2-8	2016 Sediment sampling	The OM&M surface sediment sampling design5 is a probability-based program developed around the objective of supporting rigorous, unbiased estimates of overall post-dredging average PCB concentrations, and associated uncertainty bounds, in RS1, RS2, and RS3. The data collection will be used to quantify changes in overall average surface sediment concentrations over time by river section and to support investigation of relationships among fish, water and sediment during the post-remedial monitoring period.	Unfortunately, EPA's sediment sampling design will confound the ability to use the sediment data to understand the sediment-fish relationship, as EPA will be averaging the sediment PCB concentration between pools in River Section 2 (two pools, six miles) and particularly in River Section 3 (five pools, over 28 miles). Fish in Schuylerville are not controlled by sediments in Waterford. The averaging of sediment between pools, and fish between pools, will dilute out any actual relationships. Fish in one pool are not driven by sediments in another pool. As discussed above, local surface sediments drive local fish PCBs in this system. As a result, the data necessary for the understanding of the fish-sediment relationships needs to be gathered on a pool by pool basis.	

A4-7	Appendix 4, page 3-7 to 3-8	Usability of past sediment sampling programs for temporal analysis	Ultimately, the pairing of sediment surveys to determine the rate of decay in Tri+ PCB concentrations in surface sediments is challenged by the lack of comparability among the data sets. Each survey has unique features that make direct comparison difficult and yield inconsistent rates of change. The 1991 and 1998 surveys utilized composite samples which mask the spatial heterogeneity that is more clearly defined in the dense sampling grid used during the collection of the 2002-2005 discrete samples. In particular, analysis based on sediment compositing is challenged by the difficulties of achieving true homogeneity among discrete portions when concentrations can vary by orders of magnitude, and sediment textures can vary significantly in the proportion of coarse *vs.* fine particles. The use of the available sediment survey data as an independent basis to determine the rate of decay of Tri+ PCB concentrations in surface sediments in the Upper Hudson is highly uncertain.	DEC agrees; none of the past sediment sampling programs were designed and implemented in a manner which allows for meaningful quantitative temporal analysis of trends in surface sediment PCB concentrations. EPA should not rely on such analyses, and instead rely upon the statistically representative and robust data gathering program designed and implemented by the State to understand the relationship between fish and sediment PCB concentrations on a pool by pool basis, with a monitoring program designed to achieve the data quality objectives in a time frame commensurate with the remedial targets in the ROD, ie. five years.

Re: *Hudson River Superfund Site: EPA's Five Year Review and Certificate of Completion of Remedial Action*

Dear Administrator Pruitt and Mr. Mugdan:

Please accept this letter on behalf of the New York Attorney General s Office regarding EPA s May 31, 2017 Five Year Review for the Hudson River Superfund Site. Rather than repeat the content of our previous communications to you with respect to the sufficiency and completeness of the remedial action, we enclose our September 16, 2017 letter. We also reiterate the August 30, 2017 comment letter of Basil Seggos, Commissioner of the New York State Department of Environmental Conservation.

Thank you for your consideration of the foregoing. We look forward to your response and to our continued discussions regarding the Hudson River.

Very truly yours,

Re: *Hudson River Superfund Site: EPA's Five Year Review and Certificate of Completion of Remedial Action*

Dear Administrator Enck and Mr. Mugdan:

Please accept this letter on behalf of the New York Attorney General's Office as a part of our ongoing dialogue with EPA regarding the Hudson River Superfund Site. We believe that additional steps are necessary to assure that the remedial action objectives set forth in EPA's 2002 Record of Decision ("ROD") are timely met and that the remedy is fully protective of human health and the environment. Completion of those steps is necessary before EPA issues a certificate of completion of the remedial action to GE pursuant to 42 U.S.C. § 9622(f)(3) and the November 2006 Consent Decree between EPA and GE.

EPA's issuance of the certificate of completion must comply with the statutory requirements of CERCLA Section 122(f), 42 U.S.C. § 9622(f), insofar as it will give rise to a covenant not to sue and a release from liability for GE. EPA should not predicate the certificate of completion solely upon completion of the technical engineering performance tasks undertaken pursuant to the Consent Decree. Rather, it should be issued only upon completion of the remedial action in accordance with CERCLA and only upon EPA's finding after a comprehensive review that the remedy is protective of human health and the environment, as contemplated by the ROD. The covenant that arises upon issuance of the certificate of completion is in direct conflict with CERCLA's intent absent compliance with the remedial action objectives in the ROD and completion of the remedy contemplated, and absent a fully

supported finding that the remedy is protective of human health and the environment. 42 U.S.C. § 9622(f).

Accordingly, we request that EPA, at a minimum, ensure that the remedial action objectives of the ROD and the requirements of CERCLA are met by taking the following actions:

(1) Defer issuance of a certificate of completion of the remedial action until EPA finds that the remedy is completed and is fully protective of human health and the environment in compliance with 42 U.S.C. § 9622(f)(3), (5);

(2) Determine with reasonable certainty how long it will take for the PCB concentrations in fish to drop to the levels necessary to achieve those objectives and to enable lifting human consumption health advisories for PCBs in all contaminated River reaches for all affected species;

(3) Undertake a comprehensive fish consumption survey along all contaminated reaches of the River, from Hudson Falls to the Battery, to quantify present and future human exposure to PCBs from the consumption of contaminated fish; and

(4) Define in writing the scope and objectives of the Five Year Review and the participation and respective roles of the review team members, including non-EPA members.

These issues are discussed in detail below.

(1) Defer Issuance of a Certificate of Completion of the Remedial Action until EPA Finds that the Remedy is Protective of Human Health and the Environment in Compliance with 42 U.S.C. § 9622(f)

We understand that EPA is considering issuing to GE a certificate of completion of the remedial action, notwithstanding evidence establishing the ineffectiveness of the remedy in achieving the ROD's remedial action objectives, and despite EPA's on-going Five Year Review to determine the effectiveness of the remedial action. It is inconsistent with the requirements of CERCLA Section 122(f)(3) to issue the certificate of completion without finding that the ROD's remedial action objectives have been achieved and that the remedial work necessary to achieve those objectives is complete. 42 U.S.C. § 9622(f)(3). That provision prohibits a covenant not to sue from taking effect unless EPA "certifies that the remedial action has been completed in accordance with the requirements of this chapter at the facility that is the subject of such covenant." 42 U.S.C. § 9622(f)(3). The question presented here is whether EPA can certify that the Hudson River remedial action has been completed in accordance with the requirements of CERCLA.

EPA's issuance of a certificate of completion is contrary to CERCLA's statutory scheme in the absence of a finding that the remedial action objectives of the ROD have been achieved and the remedy is protective of human health and the environment. For the Hudson River, the preeminent remedial action objective in the ROD is the reduction of the concentration of PCBs in fish within specific time-frames. *See* ROD, p. 73. It is now clear that the ROD's express remedial action objective to reach 0.4 mg/kg of PCBs in fish by 2016 has not been achieved. Based on the most recent data available, the 2014 PCB fish concentration is 2.71 mg/kg, which is more than 600% greater than the remedial objective of 0.4 mg/kg for 2016. No reasonable observer expects the upcoming 2015 or 2016 data to demonstrate that the 0.4 mg/kg concentration has now been achieved. The ROD's objective of achieving more dramatic reductions (0.05 mg/kg) later also is questionable, as EPA recognized in its 2012 Five-Year Review. *See* "First Five Year Review Report for Hudson River PCBs Superfund Site," p. 34 (2012).

In addition to the ROD's remedial action objective for PCB fish concentrations not being met, EPA has failed to provide a revised projected time-frame by which they will be met. EPA has not publicly amended the ROD or explained the significant difference between its objectives and the current status of PCB concentrations in fish. Because EPA cannot conclude that the ROD's remedial action objectives have been met, it cannot conclude that the remedial action has been completed in accordance with CERCLA's requirements. 42 U.S.C. § 122(f)(3). Consequently, a certification of completion and the associated covenant not to sue would be improper.[1]

Furthermore, a certificate of completion is premature before EPA completes its Five Year Review, which is presently underway. If EPA finds that the remedy is not protective (or if it improperly defers a protectiveness finding because of the absence of data showing declining PCBs in fish),[2] EPA may have limited recourse against GE once the certificate is issued. Indeed, EPA's finding that the remedial action has not met the ROD's standard of "protective" would be

---

[1] Unlike numerous other consent decrees for Superfund sites, the 2006 Hudson River Consent Decree does not specify that certification of the remedial action shall be issued in compliance with CERCLA Section 122(f), 42 U.S.C. § 9622(f)(3). *See, e.g., U.S. v. Atlantic Richfield Co.*, CV-83-317-HLN-SHE (D. Montana, 2008), Consent Decree, Clark Fork River Operable Unit (p. 16) ("'Certification of Completion of the Remedial Action' shall mean EPA's certification, in consultation with the State, pursuant to Section 122(f)(3) of CERCLA, 42 U.S.C. § 9622(f)(3), that the Remedial Action . . . have been completed . . . in accordance with the requirements of CERCLA, the NCP, and the ROD . . . including certification that Performance Standards have been attained."); *U.S. v. NCR Corp., et. al.*, CV-10-C-910 (E.D.Wisc. 2010), Notice of Lodging of Consent Decree (p. 14) (". . . these covenants shall take effect upon certification of completion of the remedial action by EPA pursuant to 42 U.S.C. § 9622(f)(3)"). The 2006 Hudson River Consent Decree, however, must be read as incorporating that statutory requirement.

[2] EPA's guidance indicates that deferral of a protectiveness finding in the Hudson River's Five Year Review is not appropriate because exposure pathways are well-known, no new exposure pathways have been identified, no new contaminants have been identified, and an ecological risk assessment has been done. *See* OSWER Memo 9200.2-111: "Clarifying the Use of Protectiveness Determinations for CERCLA Five-Year Reviews," p. 4 (Sept. 13, 2012).

well-supported because there continues to be human exposure to PCBs from fish consumption and the migration of PCBs down-River.

The Five Year Review is intended to assure the protectiveness of the remedy in situations where contamination remains. 42 U.S.C. § 9621(c). The purpose of the Review is directly related to determining whether a responsible party may be granted a covenant not to sue. A remedy that is not protective of human health and the environment may not be deemed by EPA as complete, and granting a covenant not to sue in those circumstances is not appropriate under the statute.

Moreover, GE has not met a fundamental requirement for a covenant not to sue under CERCLA Section 122(f). As required by CERCLA Section 122(f)(5), 42 U.S.C. § 9622(f)(5), GE has not completed all outstanding obligations under the 2006 Consent Decree including, but not limited to, work related to (1) successfully restoring all River habitat damaged during implementation of remedial work, and (2) decommissioning and decontaminating the contaminated sediment processing facility.

A certification of completion of the remedial action should not issue to GE absent EPA's finding that the ROD's remedial action objectives have been met, that the remedy is *protective,* and that GE is in compliance with, and has *completed,* all obligations under the Consent Decree within the meaning of CERCLA Section 122(f), 42 U.S.C. § 9622(f).

(2) EPA Should Determine with Reasonable Certainty the Time-Frame Necessary to Achieve the Remedial Action Objectives for the Reduction of PCB Concentrations in Fish

As discussed above, it is now clear that the remedy has not met the remedial action objective of reducing PCB concentrations in fish to 0.4 mg/kg by 2016, and may not reach the ROD's more dramatic reductions to 0.05 mg/kg. Accordingly, EPA must determine with reasonable certainty the time-frame by which there will be a reduction of PCB concentrations in fish so that fish consumption advisories for PCBs may be lifted in all contaminated River reaches of the Hudson River for all species.

New York's concurrence in the ROD was premised upon timely achieving the stated remedial action objectives for reducing PCB concentrations in fish. The State has been prejudiced not only by the failure to achieve those objectives timely, but by the current lack of certainty regarding when they will be achieved so that Hudson River fish can be safely consumed. We request that as a part of the Five Year Review process, EPA clearly define the time-frame for achieving the remedial action objectives set forth in the ROD.

In evaluating that time-frame, EPA must take into account the change in fish tissue sampling that occurred during GE's implementation of the baseline and remedial fish monitoring. The consequence of the fish data being collected in a manner that was inconsistent with what New York believed was required is important to answering the question of the time-frame for achieving the remedial objectives. This issue requires credible review by EPA.

(3) EPA's Determination of the Remedy's Protectiveness Must Be Supported By a Comprehensive Fish Consumption Survey to Quantify Current and Potential Future Human Exposure

The short- and long-term effectiveness of fish consumption advisories as an institutional control of human exposure to PCBs in edible fish is questionable. Despite the New York Department of Health's ("NYSDOH's") annual issuance of the advisories, the public is still consuming fish from the Hudson River, a circumstance of which EPA is aware. Human consumption and exposure need to be quantified and evaluated for all contaminated River reaches in order to determine whether the advisories are sufficiently protective over both the short- and long-term. In addition, the localized effects of human exposure in certain more contaminated areas of the River also should be evaluated as part of EPA's Five Year Review and protectiveness determination.

In 1996, the NYSDOH conducted a survey and found that the public was still consuming Hudson River fish in significant amounts despite extensive public outreach and widespread knowledge of the levels of PCB contamination in fish (Survey Report attached). The public's level of fish consumption and exposure that is documented in NYSDOH's Survey Report may be greater today in light of the public's understandable - but incorrect - perception that the River has been cleaned up and that the fish may safely be eaten.

An updated survey of fish consumption along all contaminated reaches of the River from Hudson Falls to the Battery should be undertaken to accurately assess current and future human exposure and the efficacy of fish consumption advisories as short- and long-term institutional controls to protect human health.

(4) The Scope and Objectives of the Five-Year Review

Presently, EPA is undertaking a second Five Year Review for the Hudson River remedy in which it is required to make a finding that human health and the environment are being protected. CERCLA § 121(c) provides:

> If the President selects a remedial action that results in any hazardous substances, pollutants, or contaminants remaining at the site, the President shall review such remedial action no less often than each 5 years after the initiation of such remedial action *to assure that human health and the environment are being protected by the remedial action* being implemented.

42 U.S.C. 9621(c) (emphasis added). Thus, fundamental to the Five Year Review is EPA's required finding that the remedy is protective.

Under applicable guidance, a protectiveness determination requires EPA to find that the remedy is functioning as intended by the ROD; that the exposure assumptions, toxicity data, cleanup levels, and remedial action objectives used at the time the remedy was selected are still valid; and that no information has come to light that could call the protectiveness of the remedy

into question. *See* EPA's "Comprehensive Five Year Review Guidance," p. 4-1 (June 2001). Given this criteria, EPA cannot make those findings now because of the flaws in the models on which the ROD was based, and because of the lack of data quantifying current human exposure.

We understand that EPA expects to complete its Five Year Review by April 2017. However, the contemplated schedule does not provide sufficient time for EPA to make the necessary finding that human health and the environment are protected, particularly in the absence of (1) fish data showing current, post-dredging PCBs levels in fish, and (2) results of a fish consumption survey quantifying current human exposure. EPA should issue the Five Year Review only if it can be well-supported. EPA's Guidance indicates that the Five Year Review team be a multi-disciplinary team with relevant technical expertise to properly review the protectiveness of the remedy. *Id.* at p. 3-1, 3-2. Rather than issue a determination that lacks sufficient data and information, EPA should expedite the generation of necessary information, such as post-dredging fish and sediment data, should immediately initiate a fish consumption survey, and should involve independent experts in evaluating the flawed models.

EPA's Five Year Review process would benefit from greater formality, such as a written scope of work identifying objectives, the participants in the process and their areas of expertise, the tasks to be undertaken, areas of responsibility, a timetable for completing the tasks, and criteria for transparency in the process. We suggest that EPA's scope of work be issued for public comment so that interested parties understand how the process will proceed.

Thank you for your consideration of the foregoing. We look forward to your response and to continuing our discussions regarding the Hudson River.

Very truly yours,

Maureen F. Leary

1996 SURVEY OF HUDSON RIVER ANGLERS

HUDSON FALLS TO TAPPAN ZEE BRIDGE AT TARRYTOWN, NEW YORK

FINAL REPORT
February 10, 2000

CERCLIS No. NYD980763841

H:\DOCUMENT\ANGLER\ANGLER.WPD

Prepared under a Cooperative Agreement with

U.S. Department of Health & Human Services
Public Health Service
Agency for Toxic Substances and Disease Registry

Summary

The Hudson River PCB (polychlorinated biphenyl) site is a National Priority List (NPL) site including about 200 miles of the Hudson River between Hudson Falls (Washington County) and the Battery in New York City. PCB contamination of fish and the potential for PCBs to cause health effects led the New York State Department of Health (NYS DOH) to issue health advisories encouraging people to limit or avoid eating fish from portions of the river and New York City Harbor. The goals of this study were to measure the awareness and understanding of the fishing public (anglers) of these health advisories and to evaluate changes in this awareness since the 1991-92 survey of anglers conducted on the river by the Hudson River Sloop Clearwater organization. The results of this assessment will be used to inform decisions concerning further education and outreach activities on the Hudson.

This survey included 172 miles of the Hudson River from Hudson Falls to the Tappan Zee Bridge at Tarrytown, but did not include the New York City area, which was surveyed in 1991-92, because of the greater complexity of interviewing anglers there. The study area was divided into three areas that correspond to the different health advisories and fishing regulations. In the Upper Hudson or Area 1 (Hudson Falls to the Federal Dam at Troy), anglers must have a fishing license and fish must be returned to the river (i.e. only catch-and-release fishing is permitted). In Area 2 (the Federal Dam at Troy to Catskill), no fishing license is required, but anglers are advised to eat no fish they catch (except American shad) from this part of the river. In Area 3 (Catskill to the Tappan Zee Bridge), anglers do not need a fishing license and only infrequent eating of fish from this part of the river is advised.

In 1996, 294 anglers fishing in the study area were interviewed about their fishing habits and awareness of health advisories on eating fish from the river. This group was more than the 166 anglers who were interviewed in the same part of the river using the same questionnaire in 1991-92. Because the two studies were very similar in design and represented a similarly broad cross-section of shoreline anglers, the changes over time in angler awareness of the advisories and the factors which influence this awareness are believed to be accurately represented. These surveys do not represent the behavior of boat anglers who may represent about half of all anglers in this part of the Hudson River. The demographic characteristics of all Hudson River anglers may also not be accurately represented by these two samples of primarily shoreline anglers.

As in 1991-92, when Hudson River anglers were also interviewed, about half the anglers knew of the state health advisories. Between the two surveys, awareness of the advisories had increased for anglers fishing in the Upper Hudson River and decreased for those fishing between Catskill and the Tappan Zee Bridge. Most anglers who knew about the advisories had learned of them through publication in the fishing regulations guide provided when they purchased a fishing license. Although a license is not required to fish in the Hudson River, three-quarters of anglers fishing between Troy and Catskill and one-third of anglers fishing between Catskill and the Tappan Zee Bridge had a license. Many anglers learned of advisories through media coverage, word-of-mouth and signs posted in the Upper Hudson.

In both surveys, more than 90% of anglers surveyed said they were fishing primarily for recreation or other similar reasons, and only 6-7% of anglers said they were fishing primarily for food. However, in both surveys, between Catskill and the Tappan Zee Bridge 13-15% of anglers said their primary reason for fishing was food and, in 1996 almost half of anglers fishing in this area said food was one of their reasons for fishing. Upstream of Catskill (in Areas 1 and 2), no one included food as a reason for fishing in 1996 and only 6-7% of 1991-92 anglers said that food was a reason for fishing. In both surveys, half of anglers reported catching fish. In 1996, a

third of all anglers had kept at least some fish that they caught, but this information was not available for the 1991-92 survey. Some anglers (18%) fishing in the Upper River(Area 1) had fish when interviewed, and a few (11%) of the anglers interviewed in Area 1 had kept more than one fish, suggesting that they may eat the fish even though they did not say so when directly asked. In both surveys, about a third of anglers said that they ate fish from the Hudson and they shared their catch with again as many individuals. Most of the individuals with whom fish were shared were women and children who NYS DOH advises to eat no fish from the Hudson.

In both surveys, the most important species (by number) caught by anglers were white perch and blue crab. Striped bass, white catfish and American eel were also important. Blueback herring were important in the 1991-92 survey, but not in 1996. Blueback herring are caught primarily in April and May, before interviewing began in 1996. In 1996 the species and size of fish kept by anglers was recorded. The most important species kept by anglers (by weight and in order) were white perch, white catfish, striped bass and carp. Largemouth and smallmouth bass, bluefish and American eel were also important. These eight species accounted for 83% (by weight) of the fish kept. The weights of blue crab could not be estimated, but crabs were the second most numerous species reported caught by anglers. Eighty three percent of all the fish kept by anglers were from the Hudson River between Catskill and the Tappan Zee Bridge where women and children are advised to eat no fish and others are advised to eat no more than a meal per month of the species that are being kept.

The species of fish kept by anglers are among the species with the highest PCB levels. Using PCB data collected from 1992 to 1996 in Area 3, PCB levels in all the species exceeded the 2 milligrams per kilogram (parts per million - ppm) action level established by the US Food and Drug Administration for fish in interstate commerce. Some anglers and others who eat Hudson River fish are being exposed to PCB levels that are a health concern and are at risk of adverse health effects. Based on ATSDR's present public health category classification (Appendix F), the Hudson River PCB site is a public health hazard. This classification is chosen based on information in the March 31, 1994 Site Review and Update for the Hudson River PCBs site and on information in this health consultation that shows that anglers and others who eat fish from the Hudson River are being exposed to levels of PCBs that are a health concern.

Until PCB levels in fish from the river decline, health advisories should continue to be issued and efforts to inform the public about these advisories should be expanded. In 1999, additional community health education efforts were undertaken to inform those who still fish in the Hudson River of the health risk posed by eating contaminated fish. The following public health actions will be implemented:

1. NYS DOH will continue to evaluate new data regarding contaminants in fish and issue appropriate health advisories as needed.
2. NYS DOH will continue to work with NYS DEC and others to distribute updated versions of the NYS DOH health advisories to anglers who fish in the Hudson River, New York Harbor and other affected marine waters.
3. NYS DOH and NYS DEC will work with local communities, state and federal agencies, non-government organizations and anglers to implement effective ways to inform anglers and others who eat Hudson River fish about the health advisories and ways to reduce their health risks from eating contaminated fish.

Table of Contents

Background and Statement of Issue

Introduction

The Hudson River PCB (polychlorinated biphenyl) site is a National Priority List (NPL) site that includes about 200 miles of the Hudson River between Hudson Falls (Washington County) and the Battery in New York City. PCBs in the site have contaminated sediments, water and fish. Because the PCB levels in fish exceed the US Food and Drug Administration action level for PCBs and because eating these fish is a health concern, the New York State Department of Health (NYS DOH) has issued health advisories. These advisories caution people to limit or avoid eating fish from the site and to limit eating striped bass, bluefish and eels from marine waters at the mouth of the Hudson River.

For almost thirty years, the General Electric Company (GE) discharged PCBs into the Hudson River from two capacitor manufacturing facilities at Hudson Falls and Fort Edward, New York (Sofaer, 1976). These discharges probably began as early as 1947 when the Fort Edward facility began operation and were substantially ended in 1977 when GE stopped using PCBs (Horn *et al.*, 1979). However, more recent information suggests that PCBs are seeping into the river from the Hudson Falls plant site (O'Brien and Gere, 1994 and 1998).

In late 1975, the New York State Department of Environmental Conservation (NYS DEC) discovered elevated PCB levels in fish from the Hudson River (Spagnoli and Skinner, 1977). In February 1976, the NYS DEC issued regulations prohibiting all fishing in the Upper Hudson River (from Hudson Falls to the Federal dam at Troy) and prohibiting commercial harvest of most fish from Troy to New York City. The public was advised to eat no fish from the Upper Hudson and to restrict consumption of fish from the rest of the river. These advisories were subsequently modified on several occasions as new data suggested that additional advisories were needed or that existing advisories could be relaxed. In 1985, the advisories were extended to striped bass caught in marine waters and commercial harvest of striped bass in marine waters was prohibited. Appendix D provides a more detailed chronology of events related to PCB contamination of the Hudson River.

For several years, the U.S. Environmental Protection Agency has been reassessing its 1984 interim decision to take no remedial action for the PCB-contaminated sediments in the Upper Hudson River (Area 1). The ecological and human health risk assessments are scheduled to be completed by August 1999. A proposed remedial action plan is currently scheduled for the end of 2000 and a Record of Decision is planned for June 2001. The most important issue is whether, in the foreseeable future, PCB levels in fish will diminish to a point that health advisories are no longer needed without additional remedial action. The known sources of PCBs to the river at the two General Electric facilities have been substantially reduced, but continued low-level releases from the facility sites and/or releases from heavily contaminated river sediments, primarily upstream of the Thompson Island Dam, may be large enough to contaminate fish for many years or could become a significant source of fish contamination in the future.

In 1989, the Agency for Toxic Substances and Disease Registry (ATSDR) completed a health assessment for the site (ATSDR, 1989). This assessment recognized that eating PCB-contaminated fish is the primary exposure pathway of concern to human health. In 1994, the NYS DOH completed a site review and update committing, among other things, to 1) continue community health education; 2) review and revise the consumption advisories; and 3) work with NYS DEC to distribute updated versions of the health advisories to anglers who fish in the Hudson River, New York City harbor and marine waters (NYS DOH, 1994). In 1996, NYS

DOH issued a Public Health Action Plan Update which reiterated these commitments and noted that new brochures were being distributed to Hudson River anglers, particularly targeted at minority and low-income groups who are less aware of the advisories (NYS DOH, 1996). In addition, the update noted that "NYS DOH [was] investigating Hudson River angler's exposure to PCBs from [eating] fish and assessing angler awareness of the advisory."

For many years, NYS DEC and NYS DOH have publicized the health advisories through annual press releases and publication in NYS DEC's fishing regulations guide given to each licensed angler. In recent years, about one million anglers purchase a fishing license each year. Since 1984, NYS DOH has published an annually revised brochure containing the statewide health advisories and additional background information. In recent years, about 20,000 copies have been distributed each year. NYS DOH staff have met with many groups to explain the advisories and county health department staff have also provided information to individuals and groups. From 1994 to 1997, NYS DEC and NYS DOH increased efforts to inform anglers in the Hudson River valley about the health advisories. The NYS DEC effort was focused on minority anglers, most of whom were unlicensed and fishing in the river downstream of the Troy dam, who appeared to be less aware of the advisory. NYS DOH distributed booklets and brochures to local health units, state parks, bait and tackle shops and a number of other groups that might provide information to unlicensed anglers.

In August 1995, fishing regulations were changed to permit catch-and-release fishing in the Hudson River between Hudson Falls and the Troy dam, a portion of the river where fishing had been prohibited since February 1976. With the 1995 change in regulations, a special brochure was prepared and distributed and signs were posted at fishing access points throughout this portion of the river informing anglers of the new regulations and PCB contamination of the fish.

Community Health Concerns

Many individuals and community groups have expressed concern that people are being exposed to unsafe levels of PCBs by eating fish from the Hudson River because many people are not aware of the advisories and others do not follow the advice. In 1991 and 1992, the Hudson River Sloop Clearwater (a not-for-profit environmental education organization in Poughkeepsie, NY) used volunteer staff to interview anglers who were fishing on the Hudson River between Hudson Falls and Staten Island about their fishing habits and awareness of health advisories. The survey found that many Hudson River anglers were not aware of the consumption advisories and others who were aware did not heed the advice (Barclay, 1993). The report highlighted health concerns for people who were eating fish from the river, particularly women of childbearing age and children under the age of 15 who appear to be at particular risk, for non-whites and for low-income people. The author concluded that the prohibition of fishing in the Upper Hudson River and the health advisories were "having only limited success in preventing unsafe levels of exposure to PCBs through consumption of Hudson River fish." The report included thirteen recommendations for improving angler awareness of, and adherence to, the health advisories, including both educational and research efforts.

In New York City, anecdotal reports have expressed concern that minorities and non-English-speaking immigrants are eating contaminated fish from the Hudson River and other waters around New York City. Some reports suggest that subsistence fishing is a concern. Others have suggested that signs and other educational materials need to be available in many languages, e.g. Spanish, Russian, Polish, Hmong, Chinese.

During the public review of this report (March 19, 1999 to May 1, 1999), several concerns were voiced in two written comments, one from an angler and the other from a public agency. Responses to these comments can be found in Appendix E.

Study Objectives

This report describes the results of a resurvey of Hudson River anglers conducted in the summer and fall of 1996. Specifically, the objectives of this study were to:

- measure awareness of the health advisories among Hudson River anglers,
- measure angler understanding of the health advisories,
- measure whether the advisories influenced fishing behavior or whether anglers eat fish,
- assess what characteristics of anglers might contribute to lack of awareness or understanding of or compliance with the advisories, and
- assess whether awareness, understanding or compliance had changed among Hudson River anglers between 1991-92 and 1996.

Site Description and Study Area

Excluding the Niagara and St. Lawrence Rivers on New York's northern border, the Hudson River is New York's largest river, with a watershed of 13,390 square miles. The Hudson River PCB site is the National Priority List (NPL) site which includes 192 miles of the Hudson River between Hudson Falls (Washington County) and the southern tip of Manhattan (Battery Park) in New York City. This survey included 172 miles of the Hudson River from Hudson Falls to the Tappan Zee Bridge (Figure 1).

For this survey, the study area was divided into areas that correspond to the different health advisories and fishing regulations:

- Area 1 - Hudson Falls to Federal Dam at Troy
- Area 2 - Federal Dam at Troy to Catskill
- Area 3 - Catskill to Tappan Zee Bridge

The advisories for Area 3 extend into the New York City Harbor waters, but because of logistical problems, the survey did not include anglers in the New York City area.

In Areas 1 and 3, the advisory and fishing regulations were different at the time of the two surveys (Table 1). In Area 1, fishing was prohibited in 1991-92, but catch-and-release fishing with a fishing license was permitted in 1996. In Area 3, the advisory recommended that no fish except American shad be eaten in 1991-92. By 1996, anglers in Area 3 were advised to restrict eating many fish to no more than one meal per month, but the advisories for women of childbearing age and children remained to eat no fish or crabs (Table 1).

Physically, the river between Hudson Falls and Troy (Upper Hudson River) is quite different from the estuarine portion of the river downstream of Troy. In the Upper Hudson River (Area 1), eight dams make the river navigable to barges and other large boats. These dams create pools which are good habitat for a variety of warmwater fish species. The dams have also slowed the downstream movement of PCB-contaminated sediments. Fish in the pool behind the first dam downstream of Hudson Falls (Thompson Island Dam) are the most heavily

Figure 1. Map of study area.

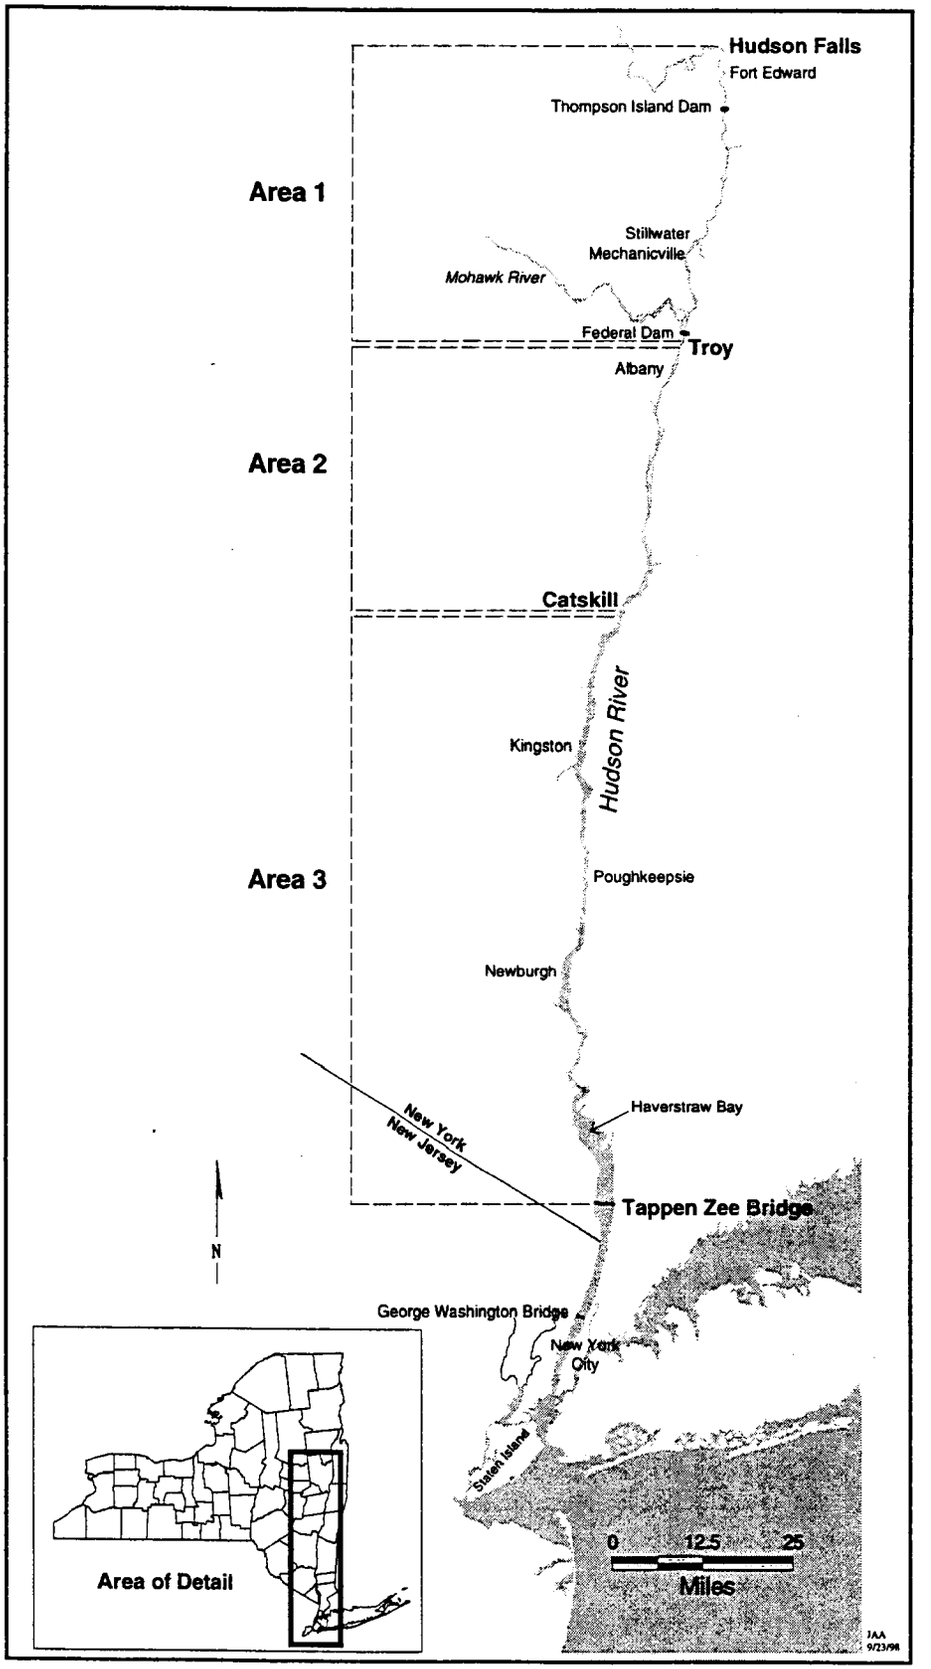

Table 1. Fishing regulations and health advisories for the Hudson River in 1991-92 and 1996.

Area of River	1991-92	1996
Area 1 Hudson Falls to Troy	Fishing prohibited. Eat NONE of any species.	Fishing permitted with license[1], possession of fish prohibited. Eat NONE of any species.
Area 2 Troy to Catskill	Fishing permitted, no license[1]. Eat NONE of any species except American shad.	Fishing permitted, no license[1]. Eat NONE of any species, except American shad.
Area 3 Catskill to Tappan Zee	Fishing permitted, no license[1]. Eat NONE of any species except American shad.	Fishing permitted, no license[1]. Infrequent eating advised[2].

[1] North (upstream) of Troy, a state fishing license is required to fish. No license is required to fish in the tidal portion of the Hudson (south or downstream of Troy).

[2] Women of childbearing age, infants and children under the age of 15 are advised to EAT NONE of any species. Other anglers are advised to eat NO MORE THAN SIX PER WEEK for blue crabs and to EAT NONE of the blue crab hepatopancreas (mustard, tomalley or liver); to eat no more than ONE MEAL PER MONTH for American eel, Atlantic needlefish, bluefish, carp, goldfish, largemouth and smallmouth bass, rainbow smelt, striped bass, walleye, white catfish and white perch; For other species, anglers are advised to eat no more than ONE MEAL PER WEEK.

contaminated, and species which anglers catch include largemouth and smallmouth bass, carp, brown and yellow bullhead, yellow perch, white sucker and several sunfish, e.g., pumpkinseed, bluegill, red-breast sunfish, rock bass (see Appendix A for scientific and common names of fish reported in these surveys to have been caught by anglers). Throughout the Upper Hudson River, fish communities are similar to one another, although American eels, white perch, blueback herring and alewife are found in the river near Troy but are not a significant component of the fish communities further up-river. Immediately upstream of the Federal dam at Troy, the Mohawk River joins the Hudson, increasing water flows by 85%.

Downstream of the Federal dam at Troy, the Hudson is an estuary subject to daily tidal cycles. Upstream of Poughkeepsie, the river is always fresh water and downstream of the George Washington Bridge at New York City the river is essentially marine throughout the year. In the estuary (Areas 2 and 3), the fisheries include a number of species not found to any significant extent in the Upper Hudson River, e.g. striped bass, American shad, white catfish, and blue crab. In the Haverstraw Bay/Tappan Zee region of the river, Atlantic tomcod and bluefish are also caught.

Methods

Survey methods

The 1996 survey used the same questionnaire and interviewing technique (with a few minor modifications) as was used in a 1991-92 survey of Hudson River anglers conducted by the Hudson River Sloop Clearwater organization (Barclay, 1993). Trained interviewers visited known fishing access sites along the Hudson River and asked anglers a series of questions (see Appendix B for a copy of the 1996 survey instrument). In 1996, the questionnaire was the same,

except that a question in the 1991-92 survey about how fish were prepared for eating was deleted and a question was added at the end of the interview that asked whether the angler had a fishing license. In the 1996 survey, interviewers identified, counted, and measured the total length of each fish being kept by anglers. In the 1991-92 survey, the species and number of fish caught were reported, but not their sizes or whether they were kept.

In 1996, an interviewer was assigned to each of the three study areas. During the course of the survey two different individuals conducted interviews in Areas 1 and 2. The interviews were conducted from early June until the end of October. Efforts were made to interview anglers on weekdays as well as weekends and at various times of the day. In 1991-92, 14 interviewers were employed to question anglers, and efforts were made to interview anglers at different times of the week and day.

The 1996 survey did not extend into the New York City metropolitan area as the 1991-92 survey did, because logistical concerns (e.g. finding qualified, multilingual interviewers; supervising their work; ensuring interviewer safety) could not be satisfactorily addressed when the survey was being planned. In the 1991-92 survey, the interviewers visited 20 different sites, but six of the sites were south of the Tappan Zee Bridge, so only 14 sites in Areas 1-3 were visited. During the course of the survey in 1996, interviewers visited the same 14 sites and an additional 18 sites. Very few anglers refused to participate, although some anglers did not respond to all questions. A few anglers did not speak English, but in almost all cases others who were fishing at the same location were able to translate for the interviewer. The actual number of these non-responders was not recorded, but they were few in number.

Data Management and Statistical Analysis

Responses from both surveys were coded and double entered into dBase IV databases. Inconsistencies were corrected and the data then transferred to SAS. Initial data analysis identified a few coding errors, and these were corrected before analysis began. Careful examination of outliers during subsequent data analysis also uncovered a few additional coding errors. The initial analyses described the cohort demographics with calculated distributions of subjects by age, gender, race/ethnicity, income, household number, and possession of a fishing license. Next, specific hypotheses were tested using summary statistics of univariate and bivariate analyses. All the tests were performed using SAS programs (SAS Institute, Cary, North Carolina). To further examine the relationship between respondents' demographic characteristics and their knowledge of health risks and water pollution, a stepwise logistic regression model was used with a 95% confidence level ($p<0.05$) for including independent variables.

Results and Discussion

In both surveys, several factors may have influenced whether the results represent anglers on the river. Ideally, anglers would have been surveyed randomly. However, the interviewing effort could not be truly randomized for date, day-of-week or time-of-day as the interviewers were part-time employees and data which would permit designing a rigorous random sampling plan were not available. Additionally, in 1996, the surveys did not get underway until June, and therefore, anglers who were fishing for American shad or striped bass in April and May, when these fish are most available in the river, were not surveyed. In both surveys, only a few boat anglers were interviewed. In May through August 1990, Green and Jackson (1991) surveyed 678 anglers fishing in the Hudson River between Stuyvesant and Kingston. They found that about half of the

angler fishing effort is from boaters. Boat anglers were found to target largemouth and smallmouth bass to a greater extent than shore anglers. In April through June 1997, Peterson (1998) assessed the striped bass fishery by aerial survey and interviews of more than 2,700 anglers. He found that 71% of angling effort and 84% of the striped bass catch was from boat anglers. Because neither the 1991-92 nor the 1996 survey interviewed very many boat anglers, the results do not adequately represent the behavior of this group.

In 1996, fewer interviews were conducted in June than in other months and most (52%) were conducted in August and September. During the 1991-92 survey, about half of interviews occurred in June and July and about 18% were conducted in May. About half of the interviews occurred on weekends in both studies. In 1996, most (51%) were conducted in the afternoon or evening (33%) and fewer (16%) were conducted in the morning. In the 1991-92 survey, the interviews were evenly distributed among morning, afternoon and evening. As noted above, during both surveys, the distribution of interviews by date, day and time may have been influenced by the interviewers availability rather than when anglers were actually fishing. Table C-1 summarizes these data (Appendix C).

In 1996, 38 different fishing locations were visited, 8 locations in Area 1, 9 locations in Area 2 and 21 locations in Area 3. A total of 294 questionnaires were completed, with almost half (48%) of the interviews being conducted in Area 3 (Table C-2). The other interviews were evenly divided among Areas 1 and 2. In 1991-92, 323 questionnaires were completed, but at the 14 sites in Areas 1, 2, and 3 (1 in Area 1, 3 in Area 2 and 10 in Area 3), 166 questionnaires were completed. The interviews were more evenly distributed among the areas than in the 1996 survey (each of the three areas had between 30% and 36% of completed questionnaires).

Within each of the three areas, the 1996 survey locations were more broadly distributed than in the 1991-92 survey (Table C-2). For example, in the 1991-92 survey, almost all (82%) of the interviews in Area 1 were from the Mechanicville to Stillwater portion. No interviews were conducted near Catskill (Area 2) or in Haverstraw Bay (Area 3). In 1996, 92 interviews (31% of all interviews) were conducted in portions of the river where no anglers were interviewed in 1991-92.

As discussed earlier, few boat anglers were interviewed and other studies indicate that they may constitute half or more of the fishing effort along the river. So, these surveys do not represent the behavior of boat anglers. These surveys did interview shoreline anglers over a broad range of fishing access sites in each of the three study Areas. The interviews were reasonably evenly distributed over the months surveyed, weekdays and weekends, and time-of-day. These data may not accurately represent the behavior of all shoreline anglers, but because the studies were very similar in design and represented similarly broad cross-sections of the angling public, the changes over time in angler awareness of the advisories and the factors which influence angler awareness are believed to be accurately represented.

Demographics

Respondents to this survey and to the 1991-92 survey had a similar distribution of age; but the distribution of genders, race and income were significantly different between the two surveys ($p<0.05$ by χ^2, see Table C-3). The majority of anglers were male in both surveys (87-93%), but women were more common in the 1996 survey (13%) than in the 1991-92 survey (8%). This difference was not statistically significant ($p>0.05$ by χ^2). In both surveys, most anglers were Caucasian (69-80%). African-Americans were represented equally in the two surveys (12-15%), but in this survey a greater proportion of the anglers were Hispanic (13% versus 4%). Asian,

Amerindian and East Indian anglers represented only 2-5% of the anglers in each survey. A large proportion (13-26%) of anglers did not provide their income bracket, but of those who did respond, almost half had annual incomes less than $30,000 and about 10% reported incomes of $50,000 or more. In 1996, about 41% of respondents from Area 3 declined to provide income information, considerably more than in the other areas (5% and 20%) and than in 1991-92 (10-16% for each of the three areas). In both surveys, about half of the anglers reported living in households of 2 or 3 people. Household sizes ranged from 1 to 12.

Awareness and understanding of the advisories

Several questions on these surveys (Questions 20, 28, 29, 31a and 31b) were designed to show how knowledgeable anglers were about fish contamination and water pollution prior to asking whether the angler were aware of "official health warnings" (Question 32). If respondents were aware of the advisories, they were asked how they learned about the advisories (Question 34) and whether and how they had changed their fishing or eating habits in response to learning of the advisories (Questions 37 and 38).

Responding to Question 32, about half of anglers said they knew of health warnings (51% in 1991-92 and 49% in 1996, see Table C-4). In 1991-92, awareness of the health advisories did not differ among the Areas, with 55% of respondents in Area 1 and 3 reporting that they knew of the health warnings and only 42% of anglers in Area 2 saying so. In 1996, the differences among the Areas were more dramatic, ranging from 75% of anglers in Area 1 aware of the health warnings to only 31% of anglers in Area 3. About 58% of anglers in Area 2 were aware of the health warnings. Other interesting patterns include:

1. License-holders were much better informed than unlicensed anglers. About 73% of anglers with a fishing license were aware of the health advisories and only 18% of unlicensed anglers knew about them.
2. In 1996, ethnic minorities were less informed than whites (13-22% compared to 63%). In the earlier survey, awareness of the advisories was more similar between minorities and whites (43-67% for minorities and 50% for whites). However, the observations for 1991-92 are based on only 34 minority responses compared to 90 minority responses in 1996, and therefore this difference may just be the result of the small sample size in 1991-92.
3. In both surveys, men were more aware that the health advisories exist than women (53-54% for men versus 18-27% for women).
4. In general, low-income respondents (less than $10,000 annual income) were less aware of the health advisories than the others (21-34% compared to 49-75%).
5. Age did not appear to dramatically influence awareness. However, in both surveys the 35-44 year-old respondents were somewhat more likely to be aware of the advisories (56% compared to 40-51% for other ages in 1996 and 72% compared to 17-52% for other ages in 1991-92). Also, in the 1991-92 survey, only 17% of respondents less than 24 years old were aware of the health advisories; but in 1996, 41% of this group were aware of the health advisories. For the other age groups, 40-72% of respondents were aware of the health advisories in both surveys.

The principal mechanism for informing New York anglers about health advisories for sportfish has been through the regulations guide provided when each licensed angler in the state purchases their license. The 1991-92 survey did not ask whether the angler had a fishing license. In 1996, somewhat more than half (58%) of the anglers said that they had a license (Table C-3). However, this percentage varied considerably by area of the Hudson River with 86% of anglers

in region 1 (where a license is required for anglers 16 years and older) saying they had a license. In Area 3, only 32% of anglers had licenses. Some people interviewed in Area 3 did not understand the concept of a fishing license.

In both surveys, the greatest proportion of respondents (37% in 1991-92 and 44% in 1996) became aware of the health advisories by reading them in the regulations guide distributed with fishing licenses (Table C-5). In 1991-92, media (35%) and word-of-mouth (24%) were the only other important sources of information. Media was the primary source of information for the majority of respondents (51%) in Area 3, and the regulations guide was more important in Areas 1 and 2. In 1996, media, posters (signs) and word-of-mouth were the source of awareness for 14-18% of respondents, but the regulations guide was the most important. In Area 1, signs were the second most important source of awareness of health advisories. Even in Area 2, where no signs have been posted, 16% of anglers reported that they became aware of health advisories from postings. The boundary between Areas 1 and 2 is an urban area and some anglers who fish in Area 2 may also fish in Area 1.

Three slightly different questions asked about potential health risks from eating fish. Question 20 asked if any fish in the immediate area of where the person was fishing were "not safe to eat". Question 28 asked if eating fish "poses a serious risk", "a slight risk" or "no risk"; and Question 31b asked "do you believe that eating fish caught at this site would pose a risk to your health?" Two other related questions asked anglers whether they thought the water was polluted (Question 29) or the fish contaminated (Question 31a) where they were fishing. If one looks at the responses of individuals who were consistent in their response to all five of these questions (i.e. answered "yes" to Questions 20, 31a and 31b and thought eating fish posed at least a slight risk and the water was at least slightly polluted), almost half (42%) of respondents responded affirmatively and only 4% consistently said that there was no pollution, no fish contamination and no health risks (Table C-6). In 1991-92, the responses were quite similar with 40% responding affirmatively and only 2% consistently denying any problem or concern. However, in 1996, the responses differed considerably among the areas. About 76% of respondents in Area 1 were consistent in affirming these concerns, while many fewer in Area 2 (46%) and Area 3 (22%) thought so. No one in Areas 1 or 2 consistently denied any problem or concern, but in Area 3 almost 9% of the respondents were consistently unconcerned. In the 1991-92 survey, the responses did not differ much by area, ranging from 33% to 52% for positive responses in each area and 2 to 4% for negative responses in each area.

In both surveys, about half of the individuals who said they were aware of the health advisories also consistently responded in the affirmative on these five questions and no one aware of the health advisories consistently denied any problem or concern. Broadly speaking, in both surveys, few black and Hispanic respondents (10-28%) consistently responded that there was a concern and 10% or fewer consistently denied any problem or concern. Income and age did not appear to influence perceptions of health risk or river pollution in any consistent way.

Multivariate analyses by means of logistic regression were performed to evaluate whether these and other demographic factors were significantly associated with responses to these five questions. The preliminary assessment suggests that, at the 95% confidence level,

- anglers who were older than 45 years had less knowledge of pollution, fish contamination and health risk issues than those who were younger,
- respondents in Area 2 and 3 had less knowledge of these concerns than those in Area 1 and
- anglers who were aware of the advisories were more likely to consistently respond affirmatively to the five questions.

This analysis suggests that gender, race, income and possession of a fishing license were not statistically significant factors in an anglers response to the five questions about pollution and health risks. Differences between surveys are probably the result of differences in demographic characteristics between the two surveys.

Although the percentages of responses were not exactly the same for the individual questions, the patterns described above were generally the same for responses to each of the five questions separately as for the combined questions.

What are Hudson River anglers catching?

Anglers were asked to identify what type of fish they were trying to catch (Question 3) and what fish they had caught (Question 5). Many anglers did not know the identity of the fish that they were catching and in some cases identifying the species referred to was difficult. For example, in some instances, names could not be made more specific than "catfish", which can mean white catfish or brown or yellow bullhead. Others like "bass" could refer to largemouth or smallmouth bass or striped bass. In the 1996 survey, when anglers had kept fish, the interviewers recorded the species, number and length of each fish.

Slightly more than half of all anglers surveyed (58% in 1991-92 and 53% in 1996) reported catching fish (Table C-7). In 1991-92, respondents in Area 1 were somewhat more successful than those from Area 2 & 3 (66% compared to 52% and 57%). But in 1996, Area 3 anglers were the most successful (70% compared to 32% of Area 1 anglers and 42% of Area 2 anglers). In the 1991-92 survey, the fish kept by anglers were not reported separately from those said to be caught. In 1996, only 30% of anglers had fish when interviewed. More than three-quarters (76%) of these anglers were fishing in Area 3 where almost half (47%) of anglers there had kept fish. In Area 1, where NYS DEC regulations prohibit keeping fish, 14 anglers (18% of those interviewed in this area) had fish when they were interviewed.

In the two surveys, 25 species of fish were reported to be caught in the three areas combined (Table C-8). About half of the total number of fish caught were white perch, blue crab or striped bass, and only 10 species account for almost 90% of the numbers caught. In 1996, anglers had kept 17 different species (Table C-9). The greatest number of anglers (45% of anglers who kept fish) had kept white perch. Striped bass, American eel, white catfish, bluefish and smallmouth bass were kept by between 10 and 17 anglers each (12-20% of anglers who kept fish). The total weights of each fish were estimated from published regressions based on length (Table C-10). The weights of all the fish kept by anglers were summed for each species and area (Table C-9). Overall, white perch was the most important species (comprising 22% of the catch by weight), followed closely by white catfish (16%) and striped bass (14%). Carp (12%), largemouth and smallmouth bass (7% each), bluefish (7%) and American eel (6%) were also somewhat important contributors to the overall catch which was kept by anglers. These eight species account for 91% of the catch by weight. Striped bass are probably more important than represented by the 1996 survey, because interviews were not conducted in April and May when the striped bass fishery is very active. In addition, blueback herring and shad are caught primarily in April and May, and their importance was therefore under-represented in the 1996 survey.

What are Hudson River anglers doing with the fish they catch?

Anglers identified up to three reasons why they were fishing. In 1996, most anglers (91%) said their primary reason for fishing was some form of "recreation", and only a small proportion

(6%) of anglers listed fishing for food as the primary reason that they were fishing (Table C-11). All of the anglers who said that they were fishing for food were actually fishing in Area 3, where they comprised 12% of anglers. Less than one quarter (23%) of all anglers included food among the reasons for fishing, but again, all of these anglers were in Area 3. Thus, almost half (47%) of anglers in Area 3 said that food was one of the reasons that they were fishing. No one in Areas 1 and 2 included food as a reason for fishing. In 1991-92, the overall responses were similar; 7% of anglers listed fishing for food as the primary reason that they were fishing. Some of these anglers were from Areas 1 and 2 (1% of all respondents). Only 16% included food among the reasons for fishing. Again, a greater proportion of anglers in Area 3 included fishing for food as a reason for fishing.

In 1996, most anglers (93%) said that they sometimes or often returned fish to the river (Table C-12). About one-third of anglers (36%) reported sometimes or often eating fish they caught from the Hudson. Some of these anglers were from Area 2 (7 anglers, 9% of respondents in Area 2), but everyone in Area 1 responded that they never ate fish they caught from the river. In Area 3, 70% of anglers reported sometimes or often eating fish from the Hudson. As noted earlier, fourteen anglers in Area 1 (18% of those interviewed in Area 1) had fish in their possession when they were interviewed. Eight of the anglers had only one fish and two anglers had three fish. Each angler said he was going to return the fish to the river, but the interviewer did not check to see that the fish were returned. Most of the 24 fish that were kept were largemouth or smallmouth bass or bluegill. Two of the bluegills were only 4 inches long and another bluegill, the rock bass and the striped bass were only 6 inches long. The other fish were all 8 inches or larger and one largemouth bass was 16 inches long. It seems likely that at least some of the fish caught in Area 1 were kept for eating. The six anglers who had more than one fish were 11% of the anglers interviewed in Area 1.

Almost one in four anglers (23%) sometimes or often gave away the fish they caught, and about 35% of anglers at least rarely gave away fish. Some of these anglers were fishing in Area 2, but everyone in Area 1 said they never gave fish away. In Area 3, almost half (46%) of anglers said they often or sometimes gave fish away, and about 65% said they gave fish away at least rarely.

Overall, only a very few individuals (two, less than 1%) reported sometimes or often selling fish, and four others (1%) said they sold fish rarely. A few individuals (4 individuals or 1%) in Area 3 did not respond when asked if they sold fish.

About 30% of anglers reported using the fish they caught for bait at least rarely. All of these anglers were in Areas 2 and 3. Very few anglers said they used the fish they caught for fertilizer (5 individuals or 2%) or threw them in the trash (9 individuals or 3%) sometimes or rarely.

In 1991-92, the pattern of responses was similar, but a greater proportion of anglers said they ate, gave away or sold the fish they caught (Table C-12). The difference in proportion of anglers who said that they ate their catch was not statistically significant, but the greater proportion who gave away or sold their fish in 1991-92 was statistically significant ($p<0.05$ by χ^2). A greater proportion of these individuals were fishing in Areas 1 and 2. All but one individual (99%) said they often or sometimes returned fish to the river. About 30% of anglers said they often or sometimes ate the fish they caught, and several were fishing in Area 1. About 40% of anglers responded that they sometimes or often gave fish away, and a few (7 individuals or 5%) said they sold fish at least rarely. Some of the anglers who said they gave fish away were fishing in Area 1. Another 12 individuals (7%) provided no response when asked if they sold fish and half of these individuals were fishing in Area 1.

In both surveys, women where less apt to eat fish from the Hudson than all anglers. In 1996,

10 of the 37 women surveyed (27%) said they ate fish from the river at least rarely. In 1991-92, two of the eleven women surveyed (18%) ate fish. In 1996, 45% of all anglers surveyed in 1996 and 40% of all anglers surveyed in 1991-92 reported eating fish from the river.

How often are Hudson River anglers eating the fish they catch?

The 133 anglers (45% of those surveyed) who said they ate fish at least rarely were asked how frequently they had eaten fish or crabs from the Hudson River during the last week (i.e. in the last 7 days) and last month (i.e. in the last 30 days). More than half (57%) had not eaten Hudson River fish or crabs in the last week and about a quarter (26%) had not eaten fish in the last month (Table C-13). About half of anglers (i.e. the median angler) who ate fish from the Hudson ate 2 meals or less in the previous month. Five percent of anglers (95th percentile consumers) reported eating 3 meals or more in the past week and 12 meals or more in the past month. Four individuals (3% of anglers who reported eating fish) said they had eaten 20 meals in the previous month.

In 1991-92, 66 anglers (40% of those surveyed) said they ate fish or crabs from the Hudson River at least rarely. More than half (65%) had not eaten fish from the Hudson in the previous week and about half (52%) had not eaten fish or crabs in the last month. Thus, the median angler ate less than one meal in the past month from the river. Five percent of anglers reported eating 3 meals or more in the past week and 10 meals or more in the past month. One individual said that he had eaten 30 meals of fish or crabs from the river in the previous month.

In 1991-92, anglers were advised to eat no fish from the study areas, so the 40% of anglers who said they ate fish were not complying with the advisories. In 1996, all anglers were advised to eat no fish caught from the river upstream of Catskill. For many species caught from the river downstream of Catskill (Area 3), men are advised to eat no more than one meal per month and women and children are advised to eat no fish. Compliance with these advisories is more complicated to calculate. The 15 anglers who said they ate fish from Area 2 and the 76 anglers who said they ate more than a meal per month of fish from Area 3 clearly ate more than is advised (Table C-13). Of the 42 individuals who said they ate one meal or less per month, five were women or younger than 15. Thus, in 1996, 96 anglers (33% of all respondents) were not following the advice provided in NYS DOH advisories. Most of these anglers (81 of the 96) were fishing in Area 3, so more than half (57%) of Area 3 anglers were eating more than is advised.

Are others eating Hudson River fish?

As noted above, about half of all anglers (45% in 1996 and 49% in 1991-92) said they gave fish away to others at least rarely (Table C-12). Most of the anglers who said they gave fish away (90% in 1996 and 85% in 1991-92) thought that the fish were eaten (Table C-14). Very few anglers acknowledged selling fish (2% in 1996 and 5% in 1991-92) or might have sold fish, assuming those who did not respond probably sold fish at least rarely (another 1% in 1996 and 7% in 1991-92).

Compared to 1991-92, many fewer anglers in 1996 said they gave fish away but did not eat the fish themselves (Table C-15). In 1996, about 8% of anglers who said they gave fish away said they did not eat the fish they caught. In 1991-92, 39% of anglers who gave fish away did not eat the fish themselves.

Anglers who responded that they ate fish at least rarely were also asked if they shared fish

that they caught with others. Some anglers were expected to share fish with family members or others that would not have been considered "given away". In both surveys, about two thirds of anglers who ate their fish (68% in 1996 and 64% in 1991-92) said that they did share fish (Table C-16). In 1996, 90 anglers shared fish with 108 other individuals, 70 of whom (65%) were women of child-bearing age and children under the age of 15. In 1991-92, 42 anglers shared fish with 96 other individuals, 42 of whom (44%) were women and children. Women of child-bearing age and children under the age of 15 are advised to eat no fish from these parts of the Hudson River (Table 1).

Environmental Contamination and Adult and Children's Health Concerns

Since 1976, NYS DEC has monitored PCB levels in fish from the Hudson River and marine waters, including the New York City Harbor (Skinner *et al.* 1996, Sloan *et al.* 1984, Sloan and Horn 1986, Sloan and Armstrong 1988, Sloan, Stang and O'Connell 1988, Sloan *et al.* 1988, Sloan and Hattala 1991, Sloan 1994, Sloan *et al.* 1995). For most of this time, some species have been collected annually from about ten different locations throughout the study area (Hudson Falls to the Tappan Zee Bridge). Generally, a standard filet is removed from each fish and each filet analyzed separately for PCBs.

In general, PCB levels in fish were quite elevated when they were first measured. With control of active discharges in the late 1970's, fish PCB levels declined precipitously for several years and continued a very slow decline until they increased dramatically in response to apparently fresh or increased discharges of PCBs near the General Electric facility at Hudson Falls which were discovered in late 1991. Since 1993, fish PCB levels have again generally begun to diminish, but they remain quite elevated (Table C-17). From 1992 to 1996 in Area 1, average PCB levels have ranged from about 6 to 61 milligrams per kilogram wet-weight or parts per million (ppm), depending on species. Largemouth and smallmouth bass comprised 58% by weight of the fish that were kept and averaged 15 and 8.0 ppm, respectively. In Areas 2 and 3, average PCB levels in fish range from less than 1 ppm to about 9 ppm. In Area 2, largemouth and smallmouth bass comprised 81% by weight of the fish that were kept and averaged 4.9 and 7.6 ppm, respectively. In Area 3, the catch was more varied. The most important six species represent 77% by weight of the fish that were kept: white perch (3.9 ppm), white catfish (8.0 ppm), striped bass (2.2 ppm), carp (no PCB data), largemouth and smallmouth bass (no PCB data). Fish that exceed the US Food and Drug Administration tolerance of 2 ppm cannot be sold in the marketplace.

PCBs cause cancer in laboratory animals exposed to high levels over their lifetimes (ATSDR, 1997). Chemicals that cause cancer in laboratory animals may also increase the risk of cancer in humans who are exposed to lower levels over long periods of time. Whether PCBs cause cancer in humans is not known.

PCBs also produce a variety of noncarcinogenic effects, primarily to the skin, liver, and to the nervous, immune and reproductive systems. Some PCBs cause birth defects in offspring born to animals exposed to high levels during pregnancy. Some studies of pregnant women suggest a link between a mother's increased exposure to PCBs from eating contaminated fish or from other environmental sources and slight effects on her child's birth weight, short-term memory, and learning. A recent study suggested that women who eat contaminated fish have slightly shorter menstrual cycles. In all these epidemiological studies, the women were also exposed to other chemicals and the effects of these chemicals on them and their children are not understood. Overall, the data from animal and human studies suggest that the fetus and newborns may be

more sensitive to PCBs than adults.

As noted above (p. 1), a previous health assessment noted that the primary exposure pathway of concern to human health was eating fish. The risks of health effects from eating fish depend primarily on contaminant concentration in the fish, how often an angler eats fish and for how many years. The available data clearly indicate that some anglers and others who eat fish from the Hudson River are being exposed to levels of PCBs that are a health concern and are at risk of adverse health effects.

Conclusions

Results from this survey and the previous one done in 1991-92 by the Hudson River Sloop Clearwater organization (Barclay, 1993) may not accurately represent all Hudson River anglers. Very few boat anglers were surveyed and information was not available to develop a random sample of the shoreline anglers. Nonetheless, a number of conclusions can be reached from the responses to these surveys:

1. Based on ATSDR's present public health category classification (Appendix F), the Hudson River PCB site is a public health hazard. This classification is chosen based on information in the March 31, 1994 Site Review and Update for the Hudson River PCBs site and on information in this health consultation. The health consultation provides data showing that anglers and others who eat fish from the Hudson River are being exposed to levels of PCBs that are a health concern.
2. Numerous anglers remained unaware of the NYS DOH health advisories for the Hudson River, particularly those who were fishing downstream of Catskill.
3. In 1996, a larger proportion of anglers in the Upper Hudson River were aware of the advisories and appear to be complying with the advice than in 1991-92. Compared to 1991-92, a greater proportion of 1996 anglers in the river between Troy and Catskill said they never ate fish they caught in the Hudson.
4. In 1996, no respondents in the Upper Hudson River said that they were eating, giving away or selling the fish they caught. However, about 18% had fish in their possession when interviewed and 11% had more than one fish. Most of the fish were largemouth and smallmouth bass or bluegill, species that are often eaten. In 1991-92, about 10% of anglers had said that they ate the fish they caught at least sometimes and almost 20% said that they gave fish away sometimes or frequently.
5. In 1996, 10% or fewer of anglers fishing between Troy and Catskill said that they ate, gave away or sold the fish they caught at least sometimes, and 8% actually had fish when interviewed.
6. In 1996, two-thirds of anglers fishing between Catskill and the Tappan Zee Bridge continued to report eating their fish at least sometimes and almost half (46%) of anglers gave fish away sometimes or frequently. More than half (57%) of anglers in this Area ate more fish than is advised by the NYS DOH advisories.
7. Overall, the difference in proportion of anglers who said they ate their catch was not significantly different, but significantly fewer anglers reported giving fish away in 1996 compared to 1991-92.
8. In 1996, half of the anglers who said they ate fish from the Hudson River reported eating two meals or less in the previous month and 5% of these anglers said they ate 12 meals or more in the previous month.

9. In 1996, 8% of anglers who did not eat the fish they caught gave them to others compared to 39% of these anglers in 1991-92.
10. Anglers who eat fish also share the fish they catch with others even though they may not say they gave the fish away. In 1996, anglers said they shared their catch with again as many other people, mostly family members. Most of these people were in the groups advised to eat no fish from the Hudson.
11. In both surveys, the fish that anglers kept were among the most contaminated species in each part of the river.
12. Both surveys suggest that most anglers became aware of the health advisories through the fishing regulations guide provided when they purchased a fishing license or through media coverage. Word-of-mouth was also important, and in 1996, signs placed along the Upper Hudson River, where most anglers had a license, appear to have contributed to improved awareness of the advisories.

Recommendations

Until the PCB levels in fish from the river decline, health advisories should continue to be issued and efforts to inform the public about the advisories should be continued. NYS DOH should continue to review data on levels of fish contamination and public health risks and revise the health advisories accordingly. The federal Agency for Toxic Substances and Disease Registry (ATSDR) and NYS DOH should continue to review all data to determine the need for additional actions at the site.

The findings of this study reinforce the recommendation in the NYS DOH 1994 Site Review and Update that "[a]dditional community health education efforts may be needed to inform those who still fish in the Hudson River of the health risk posed by PCB exposure to contaminated fish." Particular needs identified by this study and others are:

1. Additional educational efforts should be focused on the Lower Hudson River and contiguous waters with the same advisories (e.g., Harlem and East River, New York Harbor).
2. New techniques should be explored for finding those people who are eating Hudson River fish. Individuals who do not speak or read English may need to receive particular attention, especially in the New York City area.
3. Additional assessments are needed to more accurately estimate what Hudson River and New York Harbor anglers are eating, giving away or selling and to better understand how to convince anglers to follow the health advice.

Public Health Action Plan

The Public Health Action Plan (PHAP) for the Hudson River PCB site contains a description of the actions to be taken by the US EPA, ATSDR, and/or the New York State Department of Health (NYS DOH) at or near the site subsequent to the completion of this health consultation. The purpose of the PHAP is to ensure that this health consultation not only identifies public health hazards, but provides a plan of action designed to mitigate and prevent adverse human health effects resulting from exposure to hazardous substances in the environment. Included is a commitment on the part of the ATSDR/NYS DOH to follow-up on this plan to ensure that it is implemented. The following public health actions related to the health advisories for eating fish have been taken or will be implemented.

1999 Actions

1. NYS DOH evaluated 1997 data regarding PCBs and mercury in fish and modified the health advisories for some fish species between the Federal dam at Troy and Catskill.
2. NYS DOH provided the modified health advisories to NYS DEC for publication in the 1999-2000 fishing regulations guide.
3. Beginning October 1998, US EPA awarded the state a one-year grant to significantly increase education and outreach in the Hudson River estuary and New York Harbor area. NYS DOH and NYS DEC worked with local communities, state and federal agencies, non-government organizations and anglers to develop and implement effective ways to inform anglers and others who eat Hudson River fish about the health advisories and ways to reduce their health risks from eating contaminated fish. Six student intern rangers visited fishing access sites along the Hudson River from Fort Edward to New York City. They made almost 1150 site visits and spoke with almost 500 anglers, providing information about the advisories and learning about angler perceptions of them. Signs notifying anglers about the advisories were developed with assistance from three focus groups comprised of Hudson River anglers. The signs were distributed to owners or managers of marinas, parks, boat launching sites and other fishing access sites for posting along the river. Fish advisory brochures in English and Spanish were updated and distributed to bait and tackle shops, maritime museums and community groups. Radio public service announcements were prepared in Spanish and English and broadcast during prime time from mid-July through August 1999.

Actions Planned

1. NYS DOH will continue to evaluate new data regarding contaminants in fish and issue appropriate health advisories as needed.
2. NYS DOH will continue to work with NYS DEC to distribute updated versions of the NYS DOH health advisories to anglers who fish in the Hudson River, New York Harbor and other affected marine waters.
3. NYS DOH and NYS DEC will work with local communities, state and federal agencies, non-government organizations and anglers to implement effective ways to inform anglers and others who eat Hudson River fish about the health advisories and ways to reduce their health risks from eating contaminated fish.

Preparers of Report and Acknowledgments

This project was designed, managed and reported by Edward Horn (NYS DOH) with financial support under the Cooperative Agreement with the Agency for Toxic Substances and Disease Registry, Public Health Service, U.S. Department of Health and Human Services. Robert Schmidt (Hudsonia Limited and Simon's Rock College of Bard) co-authored the report. He also supervised the field effort, found and trained the interviewers and laboriously coded the data from this survey and the 1991-92 survey for computer entry. The cooperation of numerous other individuals was essential to its completion:

Dawn Breault, Dee Cotherman, Tom Lake and Erin Sawyer devoted many hours and drove many miles to interview the anglers.
Marta Gomez (NYS DOH) designed and created the data structure to facilitate analysis, supervised data entry and produced the dBase and SAS data files.
Syni-An Hwang (NYS DOH) supervised the statistical summary and analysis of the data conducted by Jean Pierre Munsie and Ying Wang. They also provide invaluable criticism and comment on early drafts of this report.
Judy Abbott (NYS DOH) prepared the figure. Tony Forti (NYS DOH) helped update the chronology of actions (Appendix D). Thomas Johnson (NYS DOH) helped prepare the description of health concerns. Pat Burl (NYS DOH) provided assistance in preparing the final report tables. Andy Mele (Hudson River Sloop Clearwater) graciously supplied the original survey forms from the 1991-92 Clearwater survey of Hudson River anglers.
Helpful comments on various versions of this report were provided by Cara Lee (Scenic Hudson), Andy Mele (Sloop Clearwater), Marian Olsen (US EPA), Doug Tomchuck (US EPA), Gregg Ulirsch (ATSDR), Walter Demick (NYS DEC), Larry Skinner (NYS DEC), Ron Sloan (NYS DEC), Patrick Festa (NYS DEC), Tony Forti, Connie Madigan (NYS DOH), Don Miles (NYS DOH), Nancy Kim (NYS DOH), Claire Pospicil (NYS DOH) and John Signor (NYS DOH).

The authors are grateful for this assistance and take full responsibility for any inadvertent omissions or errors.

Certification

The Health Consultation for the Exposure Investigation at the Hudson River PCB site was prepared by the New York State Department of Health under a cooperative agreement with the Agency for Toxic Substances and Disease Registry (ATSDR). It is in accordance with approved methodology and procedures existing at the time the health consultation was initiated.

Technical Project Officer, SPS, SSAB, DHAC

The Division of Health Assessment and Consultation (DHAC), ATSDR, has reviewed this Health Consultation and concurs with its findings.

Acting Chief, SSAB, DHAC, ATSDR

Appendix A - List of Common and Scientific Names of Fish and Crabs Reported Being Caught

Common Name	Scientific Name	Family
Alewife	*Alosa pseudoharengus*	Clupeidae
American eel	*Anguilla rostrata*	Anguillidae
American shad	*Alosa sapidissima*	Clupeidae
Atlantic silverside	*Menidia menidia*	Atherinidae
Black crappie	*Pomoxis nigromaculatus*	Centrarchidae
Blueback herring	*Alosa aestivalis*	Clupeidae
Blue crab	*Callinectes sapidus*	Portunidae
Bluefish	*Pomatomus saltatrix*	Pomatomidae
Bluegill	*Lepomis macrochirus*	Centrarchidae
Brown bullhead	*Ameiurus nebulosus*	Ictaluridae
Brown trout	*Salmo trutta*	Salmonidae
Carp	*Cyprinus carpio*	Cyprinidae
Channel catfish	*Ictalurus punctatus*	Ictaluridae
Freshwater drum	*Aplodinotus grunniens*	Sciaenidae
Golden shiner	*Notemigonus crysoleucas*	Cyprinidae
Largemouth bass	*Micropterus salmoides*	Centrarchidae
Northern pike	*Esox lucius*	Esocidae)
Pumpkinseed	*Lepomis gibbosus*	Centrarchidae
Red hake	*Urophycis chuss*	Gadidae
Rock bass	*Ambloplites rupestris*	Centrarchidae
Smallmouth bass	*Micropterus dolomieu*	Centrarchidae
Striped bass	*Morone saxatilis*	Moronidae
White catfish	*Ameiurus catus*	Ictaluridae
White perch	*Morone americana*	Moronidae
White sucker	*Catostomus commersoni*	Catostomidae
Yellow perch	*Perca flavescens*	Percidae

More than 200 species of fish have been reported from the Hudson River. The species listed above were reported caught by anglers surveyed in 1996 and 1991-92.

Appendix B - Survey Instrument

QUESTIONNAIRE - HUDSON RIVER ANGLER SURVEY, 1996

Interviewer: _____

Date: _____/_____/_____ Day of Week: _____
month day year

Time Started: _____ Time Finished: _____

Site: _____

Gender of Person Being Interviewed: M F

1) I am taking a survey of fishing activity along the Hudson River. May I ask you some questions?

_____Yes
_____No - **(THANK PERSON AND TERMINATE INTERVIEW)**

2) Have you already been interviewed this year about recreational fishing?

_____Yes - **(END INTERVIEW)**
_____No

3) What types of fish are you trying to catch? **(LIST)**

4) What fishing or crabbing equipment are you using today?
_____ Hook and line
_____ Trap
_____ Net
_____ Other: _____

5) Have you caught anything here today, and if so, what?

Species Number caught Size **(MEASURE!)**

6) How many times have you fished or crabbed on the Hudson River in the last seven days (that is from _____ until today)?

7) How many times have you fished or crabbed on the Hudson River in the last month (that is from _____ until today)?

8) What is the main reason that you fish or crab?

9) For what other reasons do you fish or crab?
(LIST IN ORDER GIVEN)

10) We would like to know what you do with the fish or crabs that you catch. Do you do any of the following with your catch- often, sometimes, rarely, or never?
(READ FROM THE LIST BELOW, CHECK EACH APPLICABLE ANSWER)

	OFTEN	SOMETIMES	RARELY	NEVER
Eat:				
Toss back:				
Fertilizer:				
Bait:				
Throw in trash:				
Give away:				
Sell:				

If you give them away, what do the people you give them to do with them?

Eat: _____
Fertilizer: _____
Bait: _____
Other: _____ **(WHAT)**
Don't know: _____

If you sell them, what do the people you sell them to do with them?

Eat: _____
Fertilizer: _____
Bait: _____
Other: _____ **(WHAT)**
Don't know: _____

11) What do you think most people here do with their catch?
(RECORD IN ORDER GIVEN)

(IF RESPONDENT DOES NOT EAT CATCH, CONTINUE. IF THEY DO EAT CATCH, SKIP TO QUESTION 17)

12) Have you ever eaten fish or crabs from here in the past?

Yes _____ **(SKIP TO QUESTION 14)**
No _____

13) Why don't you eat your catch?

(SKIP TO QUESTION 20)

14) What kind of fish or crab did you eat?
(RECORD ALL ANSWERS GIVEN)

15) How often during the fishing season did you eat these fish or crabs? **(READ ALL CHOICES)**

4 or more times a week _____
2 or 3 times a week _____
once a week _____
2 to 3 times a month _____
once a month _____
less than once a month _____

16) Why did you stop eating these fish?

(SKIP TO QUESTION 20)

(RESUME QUESTIONS HERE IF RESPONDENT DOES EAT THEIR CATCH)

17) How many times in the last week (that is from _____ until today) did you eat fish or crabs from the Hudson River?

# of meals _____ **(EMPHASIZE NUMBER OF MEALS, NOT FISH)**

18) How many times in the last month (that is from _____ until today) did you eat fish or crabs from the Hudson River?

# of meals _____ **(EMPHASIZE NUMBER OF MEALS, NOT FISH)**

19) Who, besides yourself, eats the fish or crabs you catch from this area? **(FOR EACH PERSON LISTED, RECORD THE FOLLOWING)**

-Relation to respondent
-Age
-What kind of fish or crab they eat
-Whether they eat more, the same, or less than respondent

Relation	Age	Type of fish/crab	Amount (more, same, less)

(RESUME QUESTIONING HERE WITH ALL RESPONDENTS)

20) Are there any fish or crabs that people catch here, that are not safe to eat?

Yes _____
No _____ **(SKIP TO QUESTION 26)**
No opinion/Don't know _____ **(SKIP TO QUESTION 26)**

21) What fish or crabs that people catch here are not safe to eat?

22) Is it the whole fish or crab that is not safe to eat, or just parts of them?

23) Why are they not safe to eat?

24) What would happen if you ate them?

25) If you ate these fish or crabs and had no reaction within a day or two, would that mean the fish or crabs are safe to eat?

Yes _____
No _____
Don't know _____

26) How can you tell if the fish or crabs caught here, or their parts, are safe to eat?

27) Is there any way to make the fish or crabs that are caught here safer to eat after they have been caught?

No _____
If yes, what are they?

28) For the fish or crabs that you catch here, would you say that eating them: **(READ ALL CHOICES)**

Poses no risk at all _____
Poses a slight risk _____
Poses a serious risk _____

29) Would you say the water here is: **(READ ALL CHOICES)**

Not at all polluted _____
Slightly polluted _____
Quite polluted _____

30) **(IF RESPONDENT BELIEVES THAT THE WATER IS MORE POLLUTED THAN THE FISH- COMPARE ANSWERS TO 28 & 29):** If the water is slightly/quite polluted, why does eating the fish pose no risk/a slight risk?

31) Please answer yes, no, or don't know for each of the following questions:

	Yes	No	Don't Know
-Do you think the fish you catch here are contaminated?			
-Do you believe that eating fish caught at this site would pose a risk to your health?			
-Would you like more information about the potential risks from eating fish that are contaminated			
-Would you like more information about how you can control the risks from eating contaminated fish?			

32) Do you happen to know if there are any official health warnings about eating the fish that are caught here?

Yes _____
No _____ **(SKIP TO QUESTION 39)**
Don't know _____ **(SKIP TO QUESTION 39)**

33) What warnings are you aware of?

34) How did you originally learn about them?

35) Do you happen to know who makes these health advisories?
(READ ALL CHOICES)

Federal gov't _____
State gov't _____
County _____
Town _____
Other _____
Don't know _____

36) Do you agree, disagree, or have no opinion about the following statements?

	Agree	Disagree	No Opinion
The health advisories provide me with enough information to decide whether or not to eat certain fish.			
Many of the health advisories are not needed or are exaggerated.			

37) Since you learned about the health advisories, have you made any changes in either your fishing habits or in eating the fish you catch?

Yes _____
No _____ **(SKIP TO QUESTION 39)**

38) What changes have you made since you learned of the health advisories? Do you: **(READ, CHECK EACH THAT APPLIES)**

No longer eat the fish you catch	_____
Eat less of the fish you catch	_____
Eat more of the fish you catch	_____
Clean or cook the fish differently	_____
Fish in different locations	_____
Fish less often	_____
Fish more often	_____
Change the type of fish you try to catch	_____

Other:

39) What age group are you in? **(READ)**

under 10	_____	35-39	_____
10-14	_____	40-44	_____
15-19	_____	45-49	_____
20-24	_____	50-54	_____
25-29	_____	55-59	_____
30-34	_____	60+	_____

40) What is your race or ethnic background?

41) In what range is your yearly household income before taxes? **(READ CHOICES)**

<$10,000	_____
$10,000-$29,999	_____
$30,000-$49,999	_____
$50,000-$69,999	_____
$70,000-$89,999	_____
$90,000+	_____

42) How many people are there in your household?

43) Do you have a New York fishing license?

Yes	_____
No	_____

THANK YOU VERY MUCH FOR YOUR TIME!

Appendix C - Detailed Data Tables

Table C-1. Distribution of interviews by area and time. Number and percentage of interviews conducted in each area by month, day of week and time of day.

Interview Variables		1991-92 Survey				1996 Survey			
		Area 1	Area 2	Area 3	Total	Area 1	Area 2	Area 3	Total

Tappan Zee Bridge-Croton Pt (RM 24-33)	2 (3.3)	6 (4.2)
Total	**166[1] (100)**	**294 (100)**

RM is the river mile index. The value is the number of miles along the river centerline upstream from the Battery (southern tip of Manhattan).

[1] In the 1991-92 survey, the location of 3 responses could not be accurately determined within Area 1. Thus, the totals are larger than the sum of locations that include Area 1 in 1991-92.

Table C-3. Demographic characteristics of anglers responding to 1991-92 and 1996 surveys.

Demographic Variables		1991-92 Survey				1996 Survey

[1] *Ang* is number of anglers who had at least one of the species listed. The total is the number of anglers who kept fish (from Table C-7).

[2] *n* is number of fish reported caught for that species.

[3] *Weight* is sum of weights (in grams wet-weight) estimated from regressions on length as noted in Table C-10.

N.B. In Area 2, one angler had kept 5 white catfish, but the lengths were not recorded and weights could not be estimated.

Table C-10. List of regression equations used for calculating weights of Hudson River fishes.

Species	Equation	Source
American eel	ln wt(g) = -14.631 + 3.253 ln TL(mm)	Helfman *et al.* 1984- Georgia estuary
Atlantic silverside	log wt(g) = -4.2538 + 2.5234 log TL(mm)	Wilk *et al.* 1978 - New York Bight
Bluefish	log wt(g) = -4.9533 + 3.0359 log TL(mm)	Wilk *et al.* 1978 - New York Bight
Bluegill	log wt(g) = -5.515 + 3.371 log TL(mm)	Carlander 1977 - Pennsylvania
Brown bullhead	log wt(g) = -5.061 + 3.065 log TL(mm)	Carlander 1969 - p. 535
Brown trout		Use table, p. 213 in Carlander 1969
Carp	log wt(kg) = 1.86 + 0.027 TL(cm)	Mongomery & Schmidt 1993 - Hudson River
Freshwater drum		Use table, p. 815 in Scott & Crossman 1972
Golden shiner		Use table, p 409 in Carlander 1969
Largemouth bass	log wt(g) = -5.11 + 3.117 log TL(mm)	DEC - Hudson River
Pumpkinseed	log wt(g) = -5.213 + 3.262 log TL(mm)	Carlander 1977 - Pennsylvania
Rock bass		Use table, p. 21-22 in Carlander 1977
Smallmouth bass	log wt(g) = -5.53 + 3.248 log TL(mm)	DEC - Hudson River
Striped bass	log wt(g) = -5.019 + 3.028 log TL(mm)	Hoff *et al.* 1988 - Hudson River
White catfish	log wt(g) = 5.46 + 3.24 log TL(mm)	Hughes & Carlson 1986 - Hudson River
White perch	log wt(g) = -4.9513 + 3.0249 log TL(mm)	Klauda *et al.* 1988 - Hudson River
White sucker	log wt(g) = -3.885 + 2.5914 log TL(mm)	Carlander 1969 - upstate New York

Yellow perch	-	1.14(20)	-	-	-	1.14(20)

Data from Ron Sloan, NYSDEC, on January 20, 1999. The data files are checked and updated periodically for completeness and accuracy. Values are PCB concentrations as micrograms per gram wet weight (parts per million or ppm) with the number of individual fish analyzed in parenthesis. Except where noted, PCB analyses were performed on standard fillets, quantified as Aroclors and summed. The average PCB is sample-weighted. Fish that exceed the US Food and Drug Administration tolerance of 2 ppm cannot be sold in the marketplace.

Appendix D - Chronology of PCB Actions Regarding Hudson River Fisheries

Date	Action
3/18/72	Proposed PCB tolerance level of 5.0 ppm in fish flesh - US Food and Drug Administration (FDA) action. [37 FR 5705-5707]
12/6/74	Temporary tolerance level of 5.0 ppm adopted by FDA for fish. [39 FR 42746-42748]
Fall 1975	Finding of elevated PCB levels in Hudson River fish.
2/25/76	New York State Department of Environmental Conservation (NYS DEC) Regulation (6 NYCRR 12.19) adopted prohibiting taking and possession of fish in the Hudson River and its tributaries to the first impassable falls from Fort Edward to the Federal dam at Troy. Taking of American eel prohibited throughout Hudson River. Health advisories issued concurrently.
2/26/76	Amended 6 NYCRR 12.19 to permit sale of commercially taken Atlantic sturgeon over four feet in length, goldfish and American shad.
7/14/76	The taking and sale of bait-fish in the estuarine portion of the Hudson River permitted; includes bait fish as defined in regulation plus anchovies, killifish and silversides.
7/19/76	Menhaden added as bait fish in 6 NYCRR 12.19.
4/1/77	FDA proposed lowering the temporary tolerance level for PCB in fish from 5.0 ppm to 2.0 ppm. [42 FR 17487-17494]
10/14/77	Taking of American eel in Harlem and East Rivers prohibited (6 NYCRR 12.15). Renumbered to 6 NYCRR 11.2 on 8/22/78. Renumbered and divided regulations on Hudson River fisheries 6 NYCRR 12.19 becomes 6 NYCRR 11.4 for striped bass and 6 NYCRR 11.2 for other Hudson fisheries.
3/10/78	PCB "hotspot" dredging proposal announced by DEC.
7/25/78	Data for collections of fish before and after termination of PCB discharges publically released by DEC. No significant change noted. PCB levels found to be up to 50 times the temporary tolerance level of 5.0 ppm.
11/10/78	Blueback herring, alewife, Atlantic tomcod and blue crab removed from commercial fishing closure. Striped bass commercial closure reaffirmed.

Date	Action
6/29/79	FDA announced final rule of 2.0 ppm PCB in fish effective 9/28/79. [44 FR 38330]
10/5/79	FDA confirmed date of final rule for PCBs in foods, but stayed final tolerance for fish and shellfish pending hearings. [44 FR 57389]
5/1/81	FDA announced hearings on "magnitude of the human food loss" from reduction of tolerance. [46 FR 24551-24553]
6/10/81	NYS DOH issued health advisory for blue crabs due to cadmium and PCB contamination.
10/9/81	Striped bass commercial fishing closure reaffirmed based on 1981 spring collections.
2/23/82	Emergency regulation enacted to permit taking and sale of American eel to foreign countries. Strict limitations placed on sales and foreign certification of acceptance. Commercial fishing regulation (6 NYCRR 11.2) restructured to allow all species except white catfish, white perch, carp (except as bait), and goldfish (except as ornamentals). Commercial fishing for striped bass remains prohibited under 6 NYCRR 11.4.
3/9/82	US FDA announced availability of initial decision (issued 2/8/82) regarding reduction of PCB tolerance for fish and shellfish. [47 FR 10079-10080]
4/29/82	Emergency regulation which permitted the taking and sale of American eel to foreign countries expired. All certifications were found to be unacceptable. Remainder of the restructured regulation (6 NYCRR 11.2) made permanent.
10/15/82	Striped bass commercial fishing closure reaffirmed based on PCB data from spring 1982. Findings of dibenzofurans (a contaminant of PCB) and 2,3,7,8-TCDD (dioxin) in striped bass also announced.
12/13/82	Commercial fishing restrictions and health advisories announced by New Jersey for New Jersey portions of Hudson River and New York Harbor. Restrictions essentially echo New York restrictions.
12/30/82	EPA Administrator Anne Gorsuch announced withholding $20 million allocated by Congress from New York for PCB dredging project. Commissioner Robert Flacke denounced action.

Date	Action
10/11/83	Contaminant study of waterfowl from Hudson River and other state waters announced. Study to be completed in 1985.
11/15/83	Striped bass commercial fishing closure in Hudson River again reaffirmed. Future fishing regulations for striped bass discussed with commercial fishermen. PCB levels close to the PCB temporary tolerance level of 5.0 ppm.
5/10/84	Federal funds for PCB cleanup released in an agreement that ends state lawsuit against EPA. Agreement signed in US District Court in Manhattan. Another suit for same cause had been filed by several environmental groups and the Hudson River Fishermen's Association.
5/22/84	FDA announced adoption of new PCB tolerance level for fish of 2.0 ppm, effective August 20, 1984. [49 FR 21514-21529]
6/25/84	Based on elevated PCB levels, NYS DOH added advisory to EAT NONE for carp and goldfish taken from the Hudson between Troy and Catskill.
11/15/84	NYS DOH added advisories for several Hudson River species, based on reduction of the PCB tolerance to 2 ppm.
11/30/84	Emergency regulation (6 NYCRR 36.1) prohibited use of any gill nets in Hudson River during striped bass closed season (12/1-3/14). Regulation made permanent on 2/15/85.
2/8/85	6 NYCRR 11.2 amended to prohibit commercial fishing for several additional minor fisheries (black crappie, brown bullhead, and pumpkinseed).
3/31/85	Governor Mario Cuomo announced several actions to be taken regarding striped bass in Marine District. They include: closing commercial fisheries in New York Harbor, the New York Bight and waters off western Long Island, a certification and tagging program for striped bass caught off eastern Long Island, restrictive health advisories for all striped bass, and a program of financial assistance to affected commercial fishermen.
5/1/85	Emergency regulations (6 NYCRR 11.5, 11.6 and 43.1) filed effective 5/8/85 to implement regulation of commercial harvest and sale of striped bass. Refilled on 7/12/85, 9/10/85 and 11/7/85.
5/2/85	Details of the striped bass certification and tagging program announced for eastern Long Island commercial striped bass fishery. New intensive PCB study formalized for striped bass.

Date	Action
2/18/86	New Policy on Contaminants in Fish adopted by NYS DEC. Policy formalizes NYS DEC procedures when contaminants are found in recreational and commercial fisheries.
4/18/86	Public meetings announced to discuss new findings of PCB in striped bass in the Marine District and potential regulatory alternatives.
5/5/86	Emergency regulation filed, effective 5/8/86, to prohibit all possession and sale of striped bass in New York. 6 NYCRR 11.3, 11.4, 11.5 and 11.6 consolidated into 6 NYCRR 11.3. 6 NYCRR 43.1 amended. Emergency regulation extended on 7/3/86.
7/15/86	Permanent regulation adopted prohibiting commercial and recreational taking, possession and sale of striped bass statewide. 6 NYCRR 11.3 and 43.1 consolidated into 6 NYCRR 11.3.
7/13/87	NYS DOH added advisories to EAT NONE for walleye and striped bass and EAT NO MORE THAN A MEAL PER MONTH for bluefish, northern pike taken from Troy to and including the New York Harbor.
6/21/88	NYS DOH added advisory to EAT NO MORE THAN A MEAL PER MONTH for bluefish from marine waters.
4/16/92	NYS DOH revised advisories for the Hudson south of the Troy dam for (1) black crappie, brown bullhead and pumpkinseed to EAT NO MORE THAN ONE MEAL PER WEEK from eat no more than one meal per month and (2) walleye and largemouth bass to EAT NO MORE THAN ONE MEAL PER MONTH from eat none. An advisory for smallmouth bass was added to EAT NO MORE THAN ONE MEAL PER MONTH. The advisory was revised for striped bass from the Tappan Zee Bridge south to and including the New York Harbor to EAT NO MORE THAN ONE MEAL PER MONTH from eat none. These changes were in response to new data which showed decreases in PCB levels.
7/20/93	Renumbered 6 NYCRR 36.1 which prohibited use of any gill nets in Hudson River during striped bass closed season (12/1-3/14) to 6 NYCRR 36.3.
4/21/94	NYS DOH revised advisories for the Hudson River between Troy and Catskill to EAT NONE for all species except American shad and to EAT NO MORE THAN A MEAL PER MONTH for most species from the Hudson south of Catskill. New data showed that PCB levels had increased in most species. Simplified advisory format was adopted to more clearly describe the advisories.
4/19/95	NYS DEC Commissioner Zagata requested that NYS DOH review the public health implications of allowing catch-and-release fishing in the Hudson River between Hudson Falls and Troy.

Date	Action
5/1/95	NYS DOH Commissioner DeBuono certified that there is "no compelling public health reason for keeping the Upper Hudson River closed to recreational fishing."
5/18/95	NYS DOH changed advisory for Hudson River south of Catskill from "all species" to species-by-species advisory to remove confusion regarding several salt water fish that are found in these waters. Added a clear definition for the waters of the New York Harbor where advisories apply.
5/31/95	Governor Pataki announced NYS DEC proposal to amend 6 NYCRR 10.3 and 11.2 to permit catch-and-release fishing in the Hudson River between Hudson Falls and Troy.
6/14/95	NYS DEC proposed to amend 6 NYCRR 10.3 and 11.2 to permit catch-and-release fishing in the Hudson River between Hudson Falls and Troy.
7/31/95	Comment period on the proposed amendment closed after two public meetings and hearings on 7/17 and 7/24.
8/30/95	Effective date of 6 NYCRR 10.3 and 11.2 to permit recreational catch-and-release fishing on the Hudson River between Hudson Falls and Troy.
4/4/96	NYS DOH revised advisory for striped bass taken from Jamaica Bay from eat no more than one meal per month to EAT NO MORE THAN ONE MEAL PER WEEK.

Appendix E - Interim Public Health Hazard Categories

CATEGORY / DEFINITION	DATA SUFFICIENCY	CRITERIA
A. Urgent Public Health Hazard This category is used for sites where short-term exposures (< 1 yr) to hazardous substances or conditions could result in adverse health effects that require rapid intervention.	This determination represents a professional judgement based on critical data which ATSDR has judged sufficient to support a decision. This does not necessarily imply that the available data are complete; in some cases additional data may be required to confirm or further support the decision made.	Evaluation of available relevant information* indicates that site-specific conditions or likely exposures have had, are having, or are likely to have in the future, an adverse impact on human health that requires immediate action or intervention. Such site-specific conditions or exposures may include the presence of serious physical or safety hazards.
B. Public Health Hazard This category is used for sites that pose a public health hazard due to the existence of long-term exposures (> 1 yr) to hazardous substance or conditions that could result in adverse health effects.	This determination represents a professional judgement based on critical data which ATSDR has judged sufficient to support a decision. This does not necessarily imply that the available data are complete; in some cases additional data may be required to confirm or further support the decision made.	Evaluation of available relevant information* suggests that, under site-specific conditions of exposure, long-term exposures to site-specific contaminants (including radionuclides) have had, are having, or are likely to have in the future, an adverse impact on human health that requires one or more public health interventions. Such site-specific exposures may include the presence of serious physical or safety hazards.
C. Indeterminate Public Health Hazard This category is used for sites in which "*critical*" data are *insufficient* with regard to extent of exposure and/or toxicologic properties at estimated exposure levels.	This determination represents a professional judgement that critical data are missing and ATSDR has judged the data are insufficient to support a decision. This does not necessarily imply all data are incomplete; but that some additional data are required to support a decision.	The health assessor must determine, using professional judgement, the "criticality" of such data and the likelihood that the data can be obtained and will be obtained in a timely manner. Where some data are available, even limited data, the health assessor is encouraged to the extent possible to select other hazard categories and to support their decision with clear narrative that explains the limits of the data and the rationale for the decision.
D. No Apparent Public Health Hazard This category is used for sites where human exposure to contaminated media may be occurring, may have occurred in the past, and/or may occur in the future, but the exposure is not expected to cause any adverse health effects.	This determination represents a professional judgement based on critical data which ATSDR considers sufficient to support a decision. This does not necessarily imply that the available data are complete; in some cases additional data may be required to confirm or further support the decision made.	Evaluation of available relevant information* indicates that, under site-specific conditions of exposure, exposures to site-specific contaminants in the past, present, or future are not likely to result in any adverse impact on human health.
E: No Public Health Hazard This category is used for sites that, because of the absence of exposure, do NOT pose a public health hazard.	Sufficient evidence indicates that no human exposures to contaminated media have occurred, none are now occurring, and none are likely to occur in the future	

**Such as environmental and demographic data; health outcome data; exposure data; community health concerns information; toxicologic, medical, and epidemiologic data; monitoring and management plans.*

Appendix F - Summary of Public Comments and Responses

This summary was prepared to address comments and questions on the public comment draft of the Hudson River Health Consultation. The public was invited to review the draft during the public comment period, which ran from March 19, 1999 to May 1, 1999. We received two written comments, one from an angler and the other from a public agency. Similar comments were consolidated or grouped together and some statements reworded to clarify the comment. If you have any questions about this summary, you may contact the New York State Department of Health's (NYS DOH) Outreach Unit at the toll free number: 1-800-458-1158, extension 27530.

Comment #1 - Why does this report extend into other bodies of water? It appears that you are trying "guilt by association" as a scare tactic.
Response #1 - This report commented on findings from a previous, similar study that surveyed anglers in the same part of the Hudson River but also interviewed anglers further south to the Battery and into New York City Harbor waters. The health advisories for eating fish from the Hudson River south the Tappan Zee Bridge and the New York City Harbor waters are the same as for the Hudson north of the Tappan Zee Bridge to Catskill because PCB contamination of fish is similar throughout this part of the Hudson and the New York City Harbor.

Comment #2 - Presentation of statistical analysis makes the report less readable.
Response #2 - The report was prepared for an audience with a variety of backgrounds. The summary avoided statistical jargon to improve readability for the general public.

Comment #3 -The NYS DOH is using old and outdated data. Table C-17 displays PCB data for selected fish species from 1992-1996. Newer data would show that fish are safe to eat.
Response #3 - The survey was conducted in 1996. The most recent PCB data available when the data were being analyzed were also from 1996. Because many species were not sampled in 1994-1996, we included data from earlier years to show the PCB levels in the variety of species that were sampled (see Table C-17 in the report).

Comment #4 - PCB levels in crab meat were last measured at 0.06 ppm PCB and the advisory is to eat no more than six crabs per week. Atlantic shad were 0.51 ppm yet the advice is to eat as much as you want. How is this possible?
Response #4 - Blue crabs are also contaminated with cadmium. The advisory for blue crabs is based primarily on the cadmium contamination. The health advisory notes that no one should eat more than one meal per week of fish from any fresh water, the Hudson estuary and a number of other waters around New York City. Atlantic shad are covered by this advice. Women of childbearing age, infants and children under the age of 15 are advised to not eat any fish from the Hudson estuary, including Atlantic shad. However, the advisory does note that

> "[a] few meals of Hudson River shad meat and roe, especially using cooking and trimming methods that minimize PCB content, would not pose an unacceptable health risk for women of childbearing age and children, assuming this is their only significant exposure to PCBs."

Comment #5 - Table C-17 should be expanded greatly by species, parts of fish and section of river (including Tappan Zee to the Battery) so fishermen can judge the validity of the NYS DOH health advisories.

Response #5 - For 1992-1996 and the portion of the Hudson surveyed, no other fish species were sampled than those listed in Table C-17. For most of the species listed, fish were collected from only one or two locations within each of the three reaches presented in the Table. For some individual locations within the areas that were combined for Table C-17, the number of analyses are limited and therefore the data may not represent the actual levels of PCB contamination. This table was included to show that many fish from the Hudson are significantly contaminated with PCBs. As noted in the footnote to Table C-17, the samples were standard filets (edible portions) of individual fish. With the exception of blue crabs, other parts of the fish have not been analyzed and few data are available. Samples that were analyzed as whole fish were not included in the Table as most people do not eat the whole fish.

Comment #6 - It would be helpful to clarify that this Health Consultation is not a health risk assessment and to move the objectives section prior to the background section.
Response #6 - The Environmental Contamination section has been renamed to "Environmental Contamination and Health Concerns" and a statement has been added to clearly state that a quantitative health risk assessment is beyond the scope of this report. The background discussion and description of community health concerns are presented first to provide the rationale for the study objectives.

Comment #7 - Comparison values should be incorporated in the appendices to aid in interpretation of the sampling results.
Response #7 - A newly renamed section "Environmental Contamination and Health Concerns" now includes a brief discussion of health concerns associated with exposure to PCBs such as from eating fish from the Hudson River. Reference to the United States Food and Drug Administration (FDA) tolerance level for PCBs in fish has been added to this newly renamed section and to the footnote in Table C-17. Appendix D already includes the administrative history of the FDA tolerance level (see p. 44 [3/18/72, 12/6/74, 4/1/77], p. 45 [6/29/79, 10/5/79, 3/9/82] and p. 46 [5/22/84]).

Comment #8 - A summary of PCB standards, monitoring activities and when PCB fish sampling was performed for the Hudson River and by whom should be added to the report.
Response #8 - As explained in Response #7, reference to the FDA tolerance level has been added to the report. The newly renamed section "Environmental Contamination and Health Concerns" explains in somewhat more detail the nature and extent of fish monitoring efforts on the Hudson River.

Comment #9 - Have there been any outbreaks of food-borne diseases from eating fish from the Hudson River?
Response #9 - Outbreaks of food-borne diseases from seafood are generally caused by eating inadequately cooked shellfish contaminated with bacteria, viruses or other microorganisms. Fish are rarely a source of these outbreaks.

Comment #10 - Information about background levels of PCBs in fish in the Hudson River, how often levels are monitored, clean-up efforts and health effects associated with eating PCB-contaminated fish at various levels should be available in a Fact Sheet format for the public.

Response #10 - Numerous fact sheets describing the clean-up efforts have been prepared by the US Environmental Protection Agency and NYS Department of Environmental Conservation. The health advisory booklet issued by NYS DOH includes a section describing potential health concerns associated with eating fish contaminated with PCB and other contaminants. The ATSDR has published a Toxicological Profile for PCBs that includes a Fact Sheet format discussion of health concerns related to PCB exposure including exposure from eating PCB-contaminated fish.

Comment #11 - Are there any plans to conduct a similar study in the Hudson River south of the Tappan Zee Bridge and the New York City metropolitan area?
Response #11 - At this time, the NYS DOH is not planning to conduct a similar systematic survey of anglers in the Hudson River south of the Tappan Zee Bridge and the New York City metropolitan area. However, we are focusing on educating people who may be eating fish from the Hudson and New York City metropolitan area waters about the fish advisory.

Subject: Comments on EPA's Second Five Year Review of the Hudson River Superfund Site

Dear Mr. Klawinski:

As chief executives of counties along the Hudson River Superfund Site, we have a shared interest in restoring the river's health as soon as possible. As long as unacceptable amounts of toxic PCBs remain in the Hudson, they pose a major threat to public health and economic revitalization in our waterfront communities.

The Hudson River is the keystone of the Hudson Valley's multibillion-dollar tourism economy. Plans for future economic development—including resumption of a once-vibrant commercial fishing industry and marine transport on the Champlain Canal—await completion of remediation that would fulfill the project's federally mandated goal to be "protective of human health and the environment." Dredging undertaken to date has failed to factor in decisive evidence that two to five times more contaminated sediment exist in the river than assumed at the time the EPA cleanup plan was established in 2002.

Accordingly, we call on the EPA to:

1. Declare in your Final Five-Year Review that the PCB cleanup "is not protective" of human health and the environment—as your draft review explicitly states.

2. Eliminate the draft review's finding that the remediation "will be protective." The EPA forecasts the cleanup "will be protective" in 53 years despite admitting eight additional years of research are needed to verify this claim.

3. Conduct a comprehensive cleanup of the Upper Hudson. The draft review fails to incorporate

any analysis by the National Oceanic and Atmospheric Administration and New York State Department of Environmental Conservation showing that remaining contamination in the Upper Hudson is equivalent to (in NOAA's words) "a series of Superfund-caliber sites." Both NOAA and the DEC have concluded that additional dredging is essential. An "is not protective" determination will pave the way for this to occur.

4. Undertake a remedial investigation of the Lower Hudson. The draft review admits that PCB levels in fish and sediment in the Lower Hudson remain higher than expected—that, in fact, dredging conducted to date has had little or no beneficial impact on a 160-mile portion of the Superfund site, from the Troy Dam to the Battery in Manhattan. Even more alarming, the draft review provides no plan to investigate and remove downriver contamination.

Our counties have invested considerable time, money and effort to secure a bright future for residents. Credible data indicate that additional dredging may be needed to restore the Hudson as soon as possible—safeguarding public health in communities along it, making its fish safe to eat and allowing us to realize its full economic potential. Concluding that the remedy for the entire Hudson River Superfund site is "not protective" is absolutely essential to assure the Hudson receives the cleanup it deserves.

Sincerely,

Daniel P. McCoy

Re: Draft Second Five Year Review of the Hudson River Superfund Cleanup

Dear Mr. Klawinski:

The Columbia County Environmental Management Council (EMC) consists of representatives from the County's eighteen towns and the City of Hudson, and was created under the State's Environmental Conservation Law to advise local, state and the federal government on issues related to the use, protection, and conservation of the environment for the benefit of all people.

The health of the Hudson River is inextricably linked to the environmental and economic health of all our communities. It has consequences for the air we breathe, the food we eat and sell, our drinking water, and the way we recreate. And each of these consequences has a significant impact for an economy that is heavily reliant on tourism and agriculture.

This is why we are so concerned about the conclusions stated in the Environmental Protection Agency's (EPA) Draft Second Five Year Review (FYR) of the Hudson River Superfund cleanup, mandated due to the still unknown quantities of PCB's dumped in the river by General Electric. While the EPA is claiming success for this cleanup, even the agency's own analysis shows that the effort has not reached its targeted goals and timelines, as laid out in the 2002 Record of Decision. We call upon the EPA to reconsider its conclusion, and state in the final report that the cleanup is in fact "not protective."

By law, this review is intended "to assure that human health and the environment are being protected by the remedial action being implemented." In other words, the cleanup should ensure that enough PCB 's have been removed to both protect people and help the recovery of the river's ecosystems. But the EPA's own review is actually unclear. For the upper 40 miles of the river to the Troy dam, we are told that the cleanup will, in the future, accomplish its goal. At the same time, however, it states that "more years of post-dredging data" are needed to assure long term recovery. And as for the downriver

impacts, including where Columbia County is located, the review states that it "did not predict significant impacts or major improvements from remedy implementation." In other words, there is and will be no remediation.

We knew from the outset that not all PCB's deposited by GE would be removed through this effort, but it was supposed to significantly reduce the levels of PCB's flowing downriver. Clear goals and targets were laid out for this. But one of the identified problems is that the contamination has proved to be much greater than originally estimated, in fact as much as two to four or five times greater. Thus there is much more contamination *remaining* than expected when the original goals were set. As a result, our communities will be exposed to greater levels of contaminants through the air, water, sediment, and fish for *at least a century.* What does it mean for the economic recovery counted on by local governments?

The EPA already has heard from other governmental agencies as well as independent scientists – the National Oceanic and Atmospheric Administration, the New York State Department of Environmental Conservation, the New York State Attorney General, and scientists convened by the Hudson River Foundation, among others – that the cleanup results are inadequate, *even by EPA's own measure.*

PCB contamination in the Hudson River is still a very significant threat to public health and economic prosperity. It's especially concerning that the magnitude of the threat is still not fully understood due to inadequate study. Thus it is just not credible that the EPA can state the cleanup "will be protective" in five or six decades. It is alarming that EPA considers it adequate to post fish consumption advisories. Many of the downriver communities most at risk have populations that rely on river catches for their food.

The Hudson River has been known as "America's River." It is one of our most scenic and historic American landscapes as well as a recreational and economic asset beyond measure. The Hudson River cleanup has implications for generations to come. We call upon the EPA to correct the determination reached in the Five-Year Review to say that the cleanup "is not protective" and to call for new goals and timelines.

Thank you for the opportunity to comment on this important matter.

Sincerely,

Edwin Simonsen | mtg

RE: Testimony for the Environmental Protection Agency's Public Informational Meeting about the Second, Five–Year Review of the project to remove toxic PCBs from the Hudson River.

Dear Mr. Klawinski:

The Hudson River, with its beautiful waterfronts, irreplaceable ecosystems, and rich history, is a tremendous asset to Dutchess County, and is part of what makes us "Distinctly Dutchess." Since the passage of the Clean Water Act and the advent of the environmental movement born in the Hudson Valley, the Hudson River has made a tremendous comeback; and riverfront communities that once turned their backs on this polluted waterway now look to the renewed river with waterfront plans and increased access opportunities driving private and public investments. One aspect of the river's industrial age that still holds back the Hudson's revitalization is the PCB contamination hidden in its sediments that are being continually released into the river.

The Hudson River is an irreplaceable part of our communities. The EPA has already recognized the importance of the Hudson River as one of the first rivers designated as an American Heritage River, and it remains one of the nation's most beautiful and historic. The **American Heritage Rivers** receive special attention to further three objectives: natural resource and environmental protection, economic revitalization, and historic and cultural preservation. The Hudson's ability to achieve these objectives depends on the successful completion of the PCB cleanup, which is needed to improve the economy, health and quality of life of citizens in Dutchess County and throughout the Hudson Valley.

We join Scenic Hudson and others in expressing concerns regarding the conclusions reached in the Draft Second, Five-Year Review of the PCB removal project. Terms like "short-term protective" and "will be protective" do not ensure confidence in the report's conclusions, especially when it details the lack of available after-dredging test data. Terms such as the project to date "is not protective" of human health and the environment or, at the least, "protectiveness cannot be determined" would be better supported by the report. The data and analysis in the review support such a designation:

- It explicitly admits the cleanup currently is not protective—that it will take more than 50 years of natural attenuation to achieve this.

22 Market Street, Poughkeepsie New York 12601 • (845) 486-2000 • Fax: (845) 486-2021
mmolinaro@dutchessny.gov

- The report details the portions of this project that did not go as planned including: the discovery of significantly more PCBs than anticipated; inability to progress dredging from north to south; use of a single processing site; as well as lack of reduction in PCBs in Lower Hudson. It is also states that adequate post-dredging testing has not yet occurred to determine the impact of these deviations.

- While acknowledging the need for more data, the report predicts that decades in the future, some people in the upper Hudson will be able to eat one fish meal per month. This forecast is contradicted by expert scientists at the EPA's sister federal agencies, the New York State Department of Environmental Conservation and the Hudson River Foundation. All maintain it will take a century or more to reach this target.

- Finally, the EPA concedes the lower Hudson section of the Superfund site has received no health or environmental benefits from the upriver dredging. This is the most concerning to all of the Dutchess County riverfront communities. To conclude the active remediation component of this Superfund site without even a clear understanding of the sources and causes of the PCB contamination in the Lower Hudson River is unthinkable.

Fulfilling the project's federally mandated goal—and restoring the Hudson's health—is of critical importance for sustaining Dutchess County's $528-million tourism economy responsible for nearly 10,000 jobs. It's also necessary for creating jobs based on a healthy river, including the resumption of the Hudson's once-lucrative commercial fishing industry and the annual community festivals that celebrated their catch. Communities like Beacon, Poughkeepsie and Rhinebeck have made significant investments in their waterfronts to bring people and development back to the river, so it is critical these communities and the public in general understand how the future of this superfund project may or may not impact them.

The extended comment period and public informational meetings are an important step. As the EPA considers the future of this PCB cleanup project, it is vital these concerns are addressed and responded to as part of an open and transparent process.

We will never be given this opportunity again - for our generation and those that follow - do not limit the restoration of our Hudson River. Our economy, ecology, livelihoods and future depend on it."

Sincerely,

Marcus J. Molinaro
Dutchess County Executive

DUTCHESS COUNTY
Regional CHAMBER of COMMERCE

RE: Hudson River Superfund site Final Five-Year Review

Dear Director Klawinski:

On behalf of The Dutchess County Regional Chamber of Commerce, its board of directors and the more than 1,600 member businesses and organizations, I am writing to urge your agency to continue efforts to remediate and improve the water quality along the 200-mile span of the Hudson River Superfund site.

Established in 1907, the Dutchess County Regional Chamber of Commerce is dedicated to being an advocate for employers, the authoritative information source on matters affecting business, and the unwavering champion for the region's economic health. Our objective is to be the singular leader in the Dutchess County and larger regional business community by providing positive direction and universal support in creating a dynamic and vibrant economic environment.

Dutchess County tourism represents a vital economic sector, supporting a number of local businesses. In fact, visitors to the county spent over half a billion dollars in 2016, supporting over 10,000 jobs. We encourage a high-quality standard of living for our residents and visitors and this is fueled, in large part, by the beauty of our region, especially the Hudson River and the myriad parks along it.

Building upon this momentum depends on a clean, healthy Hudson River. As long as unacceptable levels of PCBs pollute its water, sediment and fish, they hinder economic gains—both the continuation of once-lucrative industries dependent on the river and long-stalled development opportunities along it. More importantly, they continue to pose a threat to the health of people living in riverfront communities.

For 70 years, the economic, recreational, cultural and scenic values of the Hudson River have been compromised by PCB contamination. This pollution has hampered the operation of local marinas, prevented ambitious economic development opportunities, and barred generations of residents and visitors from full enjoyment of this American Heritage River.

For these reasons, we call on the EPA to:

Declare in your Final Five-Year Review that the PCB cleanup "is not protective" of human health and the environment—as your draft review explicitly states.

Delete the draft review's forecast that the remediation "will be protective" in 53 years. This assumption is made despite your admission to needing eight additional years of research to verify.

Conduct additional cleanup of the Upper Hudson. Both the National Oceanic and Atmospheric Administration and New York State Department of Environmental Conservation have concluded that without more dredging, it will take a century or longer for the Superfund project to achieve its goals. An "is not protective" determination will pave the way for the cleanup to continue.

Undertake a remedial investigation of the Lower Hudson. The draft review admits upriver dredging has had no effect on PCB contamination in the Lower Hudson—in fact, it is significantly higher than expected. The final review must layout a plan for investigating and removing this contamination.

Research confirms time and nature won't fix this project's shortcomings, as your draft review would lead us to believe. Only additional dredging will make the Hudson healthy as soon as possible. Therefore, we strongly urge the EPA to conclude that the remedy for the entire Hudson River Superfund site is "not protective." Then, and only then, can we provide the bright future our children and grandchildren deserve.

I appreciate your consideration and if I can help answer any questions or concerns, please do not hesitate to contact me at (845) 454-1700, ext. 1008.

Sincerely,

Frank M. Castella, Jr.

Re: Hudson River Superfund Five-Year Review

Dear Mr. Klawinski:
The Kingston Conservation Advisory Council (CAC) would like take this opportunity to comment on the EPA draft Five-Year Review for the Hudson River Superfund cleanup.

The Kingston CAC is an advisory body to the City of Kingston. The CAC's mission is to ensure the conservation of the City of Kingston's natural resources and the enhancement and protection of its environment while fostering unified action on environmental matters.

The City of Kingston has a population of 23,000 on the Hudson River, 100 miles south of Fort Edwards. The City has 2 miles of waterfront on the Hudson as well as 3 miles of tidal Rondout Creek waterfront. The City has one of the only public swimming beaches on the Hudson at Kingston Point. The Hudson River and Rondout Creek are important assets for water-based recreation, waterfront and economic development.

PCB contamination in the river remains a significant threat to public health and prosperity.

The EPA is to be commended for its role in the extensive removal of PCBs from the upper Hudson River, however, we ask that the report state that the remedy is NOT protective to human health and the environment. Phrases that "the remedy will be protective" should be removed.

As stakeholders directly impacted by contamination in the Hudson River, our concern is that the cleanup remedy did not work as intended, and is not protective of human health and the environment. Given that two to four times more PCBs were present than was assumed when the cleanup was designed, it is clear that more dredging needs to be carried out. This conclusion is supported by NOAA and NYSDEC; without more dredging, it will take a century or longer for the Superfund project to achieve its goals. The report must call for additional dredging of PCBs in the upper Hudson. Without additional dredging, more PCB contamination will spread further

down river threatening public health, wildlife and the economies of lower Hudson River communities.

We agree with the NYSDEC recommendation, informed by an independent evaluation of the information and data available for the site, "that investigation of the site be expanded to include performance of a Remedial Investigation and Feasibility Study for the lower Hudson, the portion of the site between the Federal Dam at Troy and the Battery in New York City." We concur with the NYSDEC conclusion that "this work is necessary to determine the nature and extent of PCB contamination in the sediments, water, and biota of the lower Hudson, and to evaluate remedial alternatives to address the currently uncontrolled, unacceptable risks to human health and the environment."

We thank you for considering our comments, and in the public interest, we urge the EPA to declare the Superfund cleanup not protective of human health and the environment, that additional dredging is needed in the upper Hudson, and that there be an investigation of contamination in the lower Hudson.

Sincerely,

Julie L. Noble

Hudson River Field Office
187 Wolf Road, Suite 303
Albany, NY 12205

Dear Gary;

I am a life-long resident of the Town of Saratoga and am completing my 14th year as supervisor of the Town of Saratoga. I am an avid bass fisherman and regularly fish the Hudson River between Fort Edward and Stillwater (catch and release only). During the past 14 years I have regularly read reports on the dredging progress and occasionally attended CAG meetings. This past year I was officially appointed a representative of Saratoga County on the CAG group. Our old Town Hall used to be located at 30 Ferry Street on the banks of the Old Champlain Canal in Schuylerville and I have personally witnessed the overflow of the old canal onto Fort Hardy Park on numerous occasions. Prior to becoming Town Supervisor I served as Historian for the Town of Saratoga and the Village of Schuylerville and documented on numerous occasions the flooding of the Beach area and Fort Hardy Park.

I am not a scientist and often have not understood the metrics described by the EPA and GE as the dredging and backfilling operations have proceeded. However, I can assure the EPA that the river did not recover immediately after stirring up the sediments as observed by me of the numerous areas where there are currently few fish and little to no vegetation. It is clear that the remedy has not been protective of the long term or even immediate health of our river or its inhabitants.

In response to the Five-Year Review Questions I submit the following:

1. Is the remedy functioning as intended by the decision documents?
   a. It is clear from the initial information on habitat and fish samples that it is taking longer for recovery than anticipated. PCB's were far deeper and more dispersed than the ROD anticipated.
   b. Habitat reconstruction has not resulted in repopulation of species within the parameters that the ROD anticipated.

c. Re-suspension and down river re-deposition of sediments into the flood plains has not been addressed.

2. Are the exposure assumptions, toxicity, data, cleanup levels, and remedial actions objections used at the time of the remedy selection still valid?
   a. The variability of testing methods has tainted the results to date.
   b. The ROD left behind significant deposits throughout the upper Hudson that are not part of the cleanup. Those deposits are in excess of standards used in other PCB cleanup projects and leave our river subject to additional cleanup costs every time we attempt a project – whether residential or public.

3. Has any other information come to light that could call into question the protectiveness of the remedy?
   a. The original Champlain Canal was not included in the remedy and it is hydro-logically part of the Hudson River. Significant PCB concentrations were found and partially removed from the canal north of Lock 5, yet the original canal was ignored. The original canal is now so silted in with blocked culverts and dead fall that it is often stagnant and overflows the banks during heavy storms.
   b. The ROD ignored the industrial and recreational use of the river when it required dredging only to the depth of the contamination – ignoring the fact that New York State has been unable to dredge to required depths for decades. Additionally, the EPA (with the ROD as an excuse) refilled areas that had silted in over the decades – impeding industrial and recreational use.
   c. The ROD focused on river sections closer to Fort Edward, ignoring contamination of the same toxicity in river sections below Lock 5. Those areas will continue to redeposit PCB's in the upper river, the flood plains and the lower river.

For these reasons – I urge the EPA to recognize that the remedy as designed is not protective. Additional dredging is required if those of us in the upper Hudson are to have a clean river. We cannot undertake projects and use of our river with the knowledge that the legacy of PCB's is still lurking in the sediments and floodplains.

Town of Stuyvesant

RESOLUTION OF 2017 IN SUPPORT OF ADDITIONAL REMEDIATION AND INVESTIGATION OF PCB CONTAMINATION IN THE HUDSON RIVER

WHEREAS, on June 1, 2017, the U.S. Environmental Protection Agency (EPA) released its Proposed Second Five-Year Review Report for Hudson River PCBs Superfund site, determining that the remedy in the Upper Hudson River — a 40-mile stretch above the Federal Dam at Troy, NY — "will be protective of human health and the environment upon completion;" and

WHEREAS, EPA did not reach a protectiveness determination for the Lower Hudson River — a 150 mile stretch below the Federal Dam; and

WHEREAS, nearly 200 miles of the Hudson River — from Hudson Falls to New York City — is a federal Superfund site because General Electric (GE) discharged millions of pounds of polychlorinated biphenyls (PCBs) into the River for thirty years, between 1947 and 1977; and

WHEREAS, PCBs are manmade, bioaccumulative, persistent pollutants that have been linked to adverse health effects including, among others: cancer, liver disorders, reduced birth weight and conception rates, persistent and significant deficits in neurological development; and

WHEREAS, the continued presence of PCBs in the Hudson River has significantly diminished economic activity and recreational use and enjoyment of the River; and

WHEREAS, New York State Department of Health has in place fishing restrictions and advisories against consumption of fish to control human exposure pathways that could result in unacceptable risks; and

WHEREAS, some may believe that the EPA's Proposed Second Five-Year Review Report does not adequately address scientific data and analyses presented by the National Atmospheric Administration and the New York State Department of Environmental Conservation that PCBs remain widespread and in greater amounts than expected throughout the Hudson River and that there is much more contamination left behind than originally estimated; and

WHEREAS, EPA determined dredging was needed to accelerate the timetable to reach remedial targets and deemed that delays of twenty years or more in reaching these targets were unacceptable;

WHEREAS, a peer-reviewed study published by the National Oceanic and Atmospheric Administration found that the remedial targets for Lower Hudson River may be reached decades longer than anticipated, since original model projections may have greatly underestimated the time to reach risk thresholds in the Lower Hudson River fish;

WHEREAS, the New York State Department of Environmental Conservation has concluded that the remedy may not be protective of human health and the environment, and that target fish tissue concentrations may not be met within time frames that EPA set out in the Record of Decision for the cleanup; and

WHEREAS, the dredging conducted by GE, which was completed years behind schedule, may not adequately allow for restoration of the Hudson River, and

WHEREAS, EPA admits that the remedy is not yet protective of human health and the environment in the Upper Hudson River, and that it will need eight or more years of fish tissue data to determine whether the remedy is effective; and

WHEREAS, EPA admits that the Lower Hudson River is not recovering as anticipated and that it needs more needs more information about PCB contamination in that stretch of the River; and

WHEREAS, the presence of toxic PCBs in the Hudson River will continue to threaten the health and well-being of Hudson Valley residents and the environment for years to come.

NOW THEREFORE BE IT RESOLVED, that the
Town of Stuyvesant hereby urges EPA to review its Proposed Second Five-Year Review Report for Hudson River PCBs Superfund Site and (1) officially declare that the cleanup may not be protective of human health and the environment;
(2) require GE to consider additional dredging in the Upper Hudson River; (3) require GE to perform any additional necessary removal of contaminated soils and sediments, including those in the Champlain Canal, to restore economic opportunities; (4) require GE to conduct a full remedial investigation of the Lower Hudson River; and (5) declare EPA's firm commitment to the restoration of the Hudson River, a significant natural and economic resource of New York State.

And further, BE IT RESOLVED that a copy of this resolution will be sent to:

- US Environmental Protection Agency – Region 2 and Hudson River Field Office
- John Flannery, Chairman and CEO, General Electric Corporation
- New York State Governor Andrew Cuomo
- NYS Office of the Attorney General
- NYS Department of Environmental Conservation
- NYS Canal Corporation
- National Oceanic and Atmospheric Agency
- US Department of Interior Fish and Wildlife Service
- Hudson River Congressional Delegation

Re: Hudson River Superfund Five-Year Review

Dear Mr. Klawinski:

I appreciate the opportunity to comment on behalf of New York's Ulster County Environmental Management Council regarding the EPA draft Five-Year Review for the Hudson River Superfund cleanup. The Ulster County Environmental Management Council is comprised of appointed representatives from the county's conservation advisory councils, commissions and boards in addition to at-large members.

There are twenty-four local governments in Ulster County which have a total population of about 182,000. Ulster County communities share many miles of shoreline with the lower Hudson River and two of our communities draw drinking water from the Hudson River. These factors give our council a unique interest in the health of the river. The Hudson River is an important asset for drinking water, water-based recreation, waterfront and economic development.

The EPA is to be commended for its role in the extensive removal of PCBs from the Upper Hudson River; however, we take exception to the conclusion in the draft Five-Year Review that the remedy for cleanup has resulted in protecting human health and the environment.

When considering remedies to address PCB contamination in the Hudson, the EPA determined that cancer and non-cancer health risks were well above the acceptable risk range for people who ate fish from both the upper and lower Hudson. The Superfund cleanup remedy was intended to address the risks, and the Five-Year Review is intended to ensure the risks have been adequately addressed

As stakeholders directly impacted by contamination in the Hudson River, our concern is that the cleanup remedy is not working as intended, and is not protective of human health and the environment. Given that two-to-three times as many PCBs remain in the river than expected, it is clear that more cleanup is needed. Without additional cleanup, PCB contamination will spread further down river threatening public health, wildlife and the much needed economic development of the lower Hudson River communities.

In its Hudson River PCB Superfund Summary Fact Sheet, EPA acknowledges PCB concentrations in fish in the Upper Hudson have not yet reached protective levels, though average PCB concentrations are

declining. EPA states, it "believes it is likely that improvement will occur gradually over several decades, at least."

The National Oceanic and Atmospheric Administration, the New York State Department of Environmental Conservation (NYSDEC) and the Hudson River Foundation have compiled data and have concluded the river will not recover for many decades beyond the cleanup goals established by EPA. This means the public who use the Hudson River will continue to be exposed to high levels of PCBs through air, water, sediment, and fish for possibly - another century. For those who use the river for recreation as well as those who live and work along the river, continued exposure to high levels of PCBs through air, water, sediment and fish for many decades is unacceptable.

We agree with the NYSDEC recommendation, informed by an independent evaluation of the information and data available for the site, "that investigation of the site be expanded to include performance of a Remedial Investigation and Feasibility Study for the lower Hudson, the portion of the site between the Federal Dam at Troy and the Battery in New York City." We concur with the NYSDEC conclusion that "this work is necessary to determine the nature and extent of PCB contamination in the sediments, water, and biota of the lower Hudson, and to evaluate remedial alternatives to address the currently uncontrolled, unacceptable risks to human health and the environment."

We thank you for considering our comments, and in the public interest, we urge the EPA to declare the Superfund cleanup not protective of human health and the environment, that additional dredging is needed, and more must be done to ensure the health of the river.

Yours truly,

Dave Haldeman, Chair
Ulster County Environmental Management Council

September 1, 2017

Gary Klawinski
Hudson River Field Office
187 Wolf Road, Suite 303
Albany, NY 12205

Dear Mr. Klawinski,

For the last 4 years I have represented the village of Schuylerville, first as a trustee and now as Mayor. For nineteen years I have experienced the high flows, the dredging and the moods of the river in all seasons and in all weather. I am not a scientist and quite often have not understood the metrics described by the EPA and GE as the dredging and backfilling operations have proceeded. However, I can assure the EPA that the river did not recover immediately after stirring up the sediments. It is clear that the remedy has not been protective of the long term or even immediate health of our river or its inhabitants.

Of particular concern is repeated flooding of the original Champlain Canal now plugged with sediment and un able to fulfill its 100+ year role as the collector of run off water from the Village streets and storm sewers. The recent overflows of the canal's banks threaten a serious breach which would cause the canal water to flow directly into Ft. Hardy Park over its many playing fields and possibly contaminate the critical location of the well heads of the municipal water system. Since the original canal is hydrologically part of the River at the level ABOVE lock C5 such a breach could prove catastrophic. We cannot even touch the sediments now trapped in the original canal for fear of violating the disposal protocols of the recent dredging operations. We desperately need an intervention in this threatening situation.

Further, In response to the Five-Year Review Questions I repeat the conclusions of our local working group:

1. Is the remedy functioning as intended by the decision documents? NO
   a. It is clear from the initial information on habitat and fish samples that it is taking longer for recovery than anticipated. PCB's were far deeper and more dispersed than the ROD anticipated.
   b. Habitat reconstruction has not resulted in repopulation of species within the parameters that the ROD anticipated.
   c. Resuspension and down river redisposition of sediments into the flood plains has not been addressed.

2. Are the exposure assumptions, toxicity, data, cleanup levels, and remedial actions objections used at the time of the remedy selection still valid? NO
   a. The variability of testing methods has tainted the results to date.
   b. The ROD left behind significant deposits throughout the upper Hudson that are not part of the cleanup. Those deposits are in excess of standards used in other PCB cleanup projects and leave our river subject to additional cleanup costs every time we attempt a project – whether residential or public.

3. Has any other information come to light that could call into question the protectiveness of the remedy? MOST DEFINITELY YES
   a. The original Champlain Canal was not included in the remedy and it is hydrologically part of the Hudson River. Significant PCB concentrations were found and partially removed from the canal north of Lock 5, yet the original canal was ignored. The original canal is now so silted in with blocked culverts and dead fall that it is often stagnant and overflows the banks during heavy storms.
   b. The ROD ignored the industrial and recreational use of the river when it required dredging only to the depth of the contamination – ignoring the fact that New York State has been unable to dredge to required depths for decades. Additionally, the EPA (with the ROD as an excuse) refilled areas that had silted in over the decades – impeding industrial and recreational use.
   c. The ROD focused on river sections closer to Fort Edward, ignoring contamination of the same toxicity in river sections below Lock 5. Those areas will continue to redeposit PCB's in the upper river, the flood plains and the lower river.

For these reasons – I urge the EPA to recognize that the remedy as designed is not protective. Additional dredging is required if those of us in the upper Hudson are to have a clean river. We cannot undertake projects and use of our river with the knowledge that the legacy of PCB's is still lurking in the sediments and floodplains.

Sincerely yours,

Dan Carpenter

Dear Gary;

I am a resident of the Town of Saratoga and walk along the Hudson River in the Towns of Saratoga and Northumberland nearly every day. For the last 4 years I have represented the village of Schuylerville, first as a trustee and now as mayor. For nineteen years I have experienced the high flows, the dredging and the moods of the river in all seasons and in all weather.

I am not a scientist and quite often have not understood the metrics described by the EPA and GE as the dredging and backfilling operations have proceeded. However, I can assure the EPA that the river did not recover immediately after stirring up the sediments. It is clear that the remedy has not been protective of the long term or even immediate health of our river or its inhabitants.

In response to the Five-Year Review Questions:

Is the remedy functioning as intended by the decision documents? NO
It is clear from the initial information on habitat and fish samples that it is taking longer for recovery than anticipated. PCB's were far deeper and more dispersed than the ROD anticipated. Habitat reconstruction has not resulted in repopulation of species within the parameters that the ROD anticipated.
Resuspension and down river redisposition of sediments into the flood plains has not been addressed.

Are the exposure assumptions, toxicity, data, cleanup levels, and remedial actions objections used at the time of the remedy selection still valid? NO

The variability of testing methods has tainted the results to date.
The ROD left behind significant deposits throughout the upper Hudson that are not part of the cleanup. Those deposits are in excess of standards used in other PCB cleanup projects and leave our river subject to additional cleanup costs every time we attempt a project – whether residential or public.

Has any other information come to light that could call into question the protectiveness of the remedy? MOST DEFINITELY YES
The original Champlain Canal was not included in the remedy and it is hydrologically part of the Hudson River. Significant PCB concentrations were found and partially removed from the canal

north of Lock 5, yet the original canal was ignored. The original canal is now so silted in with blocked culverts and dead fall that it is often stagnant and overflows the banks during heavy storms.

The ROD ignored the industrial and recreational use of the river when it required dredging only to the depth of the contamination – ignoring the fact that New York State has been unable to dredge to required depths for decades. Additionally, the EPA (with the ROD as an excuse) refilled areas that had silted in over the decades – impeding industrial and recreational use.

The ROD focused on river sections closer to Fort Edward, ignoring contamination of the same toxicity in river sections below Lock 5. Those areas will continue to redeposit PCB's in the upper river, the flood plains and the lower river.

For these reasons – I urge the EPA to recognize that the remedy as designed is not protective. Additional dredging is required if those of us in the upper Hudson are to have a clean river. We cannot undertake projects and use of our river with the knowledge that the legacy of PCB's is still lurking in the sediments and floodplains.

Subject: Comments on EPA's Second Five Year Review of the Hudson River Superfund Site

Dear Mr. Klawinski:

As chief executives of counties along the Hudson River Superfund Site, we have a shared interest in restoring the river's health as soon as possible. As long as unacceptable amounts of toxic PCBs remain in the Hudson, they pose a major threat to public health and economic revitalization in our waterfront communities.

The Hudson River is the keystone of the Hudson Valley's multibillion-dollar tourism economy. Plans for future economic development—including resumption of a once-vibrant commercial fishing industry and marine transport on the Champlain Canal—await completion of remediation that would fulfill the project's federally mandated goal to be "protective of human health and the environment." Dredging undertaken to date has failed to factor in decisive evidence that two to five times more contaminated sediment exist in the river than assumed at the time the EPA cleanup plan was established in 2002.

Accordingly, we call on the EPA to:

1. Declare in your Final Five-Year Review that the PCB cleanup "is not protective" of human health and the environment—as your draft review explicitly states.

2. Eliminate the draft review's finding that the remediation "will be protective." The EPA forecasts the cleanup "will be protective" in 53 years despite admitting eight additional years of research are needed to verify this claim.

Office of the County Executive

Michaelian Office Building
White Plains, New York 10601 Telephone: (914) 995-2900 E-mail: ce@westchestergov.com

3. Conduct a comprehensive cleanup of the Upper Hudson. The draft review fails to incorporate any analysis by the National Oceanic and Atmospheric Administration and New York State Department of Environmental Conservation showing that remaining contamination in the Upper Hudson is equivalent to (in NOAA's words) "a series of Superfund-caliber sites." Both NOAA and the DEC have concluded that additional dredging is essential. An "is not protective" determination will pave the way for this to occur.

4. Undertake a remedial investigation of the Lower Hudson. The draft review admits that PCB levels in fish and sediment in the Lower Hudson remain higher than expected—that, in fact, dredging conducted to date has had little or no beneficial impact on a 160-mile portion of the Superfund site, from the Troy Dam to the Battery in Manhattan. Even more alarming, the draft review provides no plan to investigate and remove downriver contamination.

Our counties have invested considerable time, money and effort to secure a bright future for our residents. Credible data indicates that additional dredging may be needed to restore the Hudson as soon as possible—safeguarding public health in communities along it, making its fish safe to eat and allowing us to realize its full economic potential. Concluding that the remedy for the entire Hudson River Superfund site is "not protective" is absolutely essential to assure the Hudson receives the cleanup it deserves.

Sincerely,

Robert P. Astorino

RE: Hudson River Cleanup (https://www3.epa.gov/hudson/)

Dear Director Klawinski:

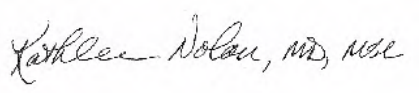
Catskill Mountainkeeper is a nationally recognized advocate for the Hudson Valley and Catskill region. Working with a network of more than 40,000 concerned citizens and strategic partners, Mountainkeeper's programs protect and promote our region's extraordinary natural heritage, while promoting smart development that supports local communities and grows our economy in a sustainable way.

Catskill Mountainkeeper urges the Environmental Protection Agency to insist that cleanup of polychlorinated biphenyls from the Hudson River be comprehensive. PCBs are toxic to humans and wildlife, and the river does not have any mechanism to rid itself of these contaminants. Instead, PCBs linger and gradually disperse into the environment, contaminating water and air and accumulating over time to dangerous levels. Exposure to aerosolized PCBs has been studied in sites near the Hudson River and has been shown to increase our risk of cancer, hypertension, heart disease, diabetes, and cancer. High-level accumulations of PCBs in fish make them too toxic for humans to eat.

General Electric dumped high concentrations of PCBs into the Hudson River, and if General Electric does not remove more of them, we are left with a 200-mile long Superfund site that is a danger to the health of anyone who breathes the air along the river or who boats on it or fishes in it.

Our clean-up efforts now are our best opportunity to return the Hudson River toward its original pristine and life-giving conditions. We know how this problem occurred (PCBs were introduced by humans into the river) and we know how to fix it (we go into the river with specialized equipment and remove them). We must demand that General Electric do its clean-up job as completely as possible, giving us back a safe and healthy river that is ready for us to enjoy now and into the future.

Sincerely,



Kathleen Nolan, MD, MSL
Senior Research Director
Catskill Mountainkeeper

September 1, 2017

Gary Klawinski
Director, Hudson River Field Office
U.S. Environmental Protection Agency
187 Wolf Road, Suite 303
Albany, NY 12205

Dear Mr. Klawinski:

We represent businesses along the 200-mile span of the Hudson River Superfund site. The river is the bedrock of the Hudson Valley's current and future economic vitality. It drives the region's multibillion-dollar tourism industry and is in large part responsible for the ongoing recovery of the real estate market in the Lower Hudson since the great recession. The beauty of the river and the myriad parks along it contribute significantly to residents' quality of life and serve as catalysts for attracting visitors and new jobs.

Building upon this momentum depends on a clean, healthy Hudson River. As long as unacceptable levels of PCBs pollute its water, sediment and fish, they hinder lasting economic gains—both the resumption of once-lucrative industries dependent on the river and long-stalled development opportunities along it. More important, they continue to pose a threat to the health of people living in riverfront communities.

For 70 years, the economic, recreational, cultural and scenic values of the Hudson River have been compromised by PCB contamination. This pollution has destroyed a once-vibrant commercial fishing industry, hampered the operation of marinas, led to a severe curtailment of marine transport on the Champlain Canal, tripled the costs of dredging the NY-NJ Harbor, prevented ambitious economic development opportunities on the Upper Hudson similar to those being realized along the Mohawk River, and barred generations of residents and visitors from full enjoyment of this American Heritage River.

For these reasons, we call on the EPA to:

Declare in your Final Five-Year Review that the PCB cleanup "is not protective" of human health and the environment—as your draft review explicitly states.

Delete the draft review's forecast that the remediation "will be protective" in 53 years. You make this assumption despite your own admission that it will take eight additional years of research to verify.

Conduct additional cleanup of the Upper Hudson. Both the National Oceanic and Atmospheric Administration and New York State Department of Environmental Conservation have concluded that without more dredging, it will take a century or longer for the Superfund project to achieve its goals. An "is not protective" determination will pave the way for the cleanup to continue.

Undertake a remedial investigation of the Lower Hudson. The draft review admits that upriver dredging has had no effect on PCB contamination in the Lower Hudson—in fact, it is significantly higher than expected. The final review must lay out a plan for investigating and removing this contamination.

Data confirm that time and nature won't fix this project's shortcomings, as your draft review would lead us to believe. Only additional dredging will make the Hudson healthy as soon as possible. Therefore, we strongly urge the EPA to conclude that the remedy for the entire Hudson River

Superfund site is "not protective." Then and only then can we begin to plan for the bright future our children and grandchildren deserve.

Subject: Re: FYR Team presentation

Its okay John, I have been asking the same first question for 16+ years..... I would also like to point out that in Question A, 62%-72% of what? The mass in the ROD of 3.2 million lbs. is quite different than the later discovered 5 million lbs. Which number is correct? It's a tale of two rivers! Though fish are important, the plight of the marinas in the lower river who cannot dispose of contaminated dredge spoils will go on much longer.
Best!
Gil

RIVERKEEPER
NY's clean water advocate

July 7, 2017

The Honorable Charles Schumer
Peekskill Regional Office,
One Park Place, Suite 100
Peekskill, NY 10566

Dear Senator Schumer:

I am writing on behalf of Riverkeeper, Inc.—a member-supported environmental watchdog organization dedicated to defending the Hudson River and its tributaries and to protecting the drinking water supply of nine million New York City and Hudson Valley residents—to urge you to ask the Environmental Protection Agency ("EPA") to hold a public information meeting in New York City regarding the Proposed Second Five-Year Review of the General Electric ("GE") PCB Superfund Site ("FYR Report"). The recently released FYR Report includes a misguided determination that the cleanup to date "will be protective of human health and the environment" in the Upper Hudson River, a 40-mile stretch above the Federal Dam in Troy, NY, despite the agency's admission that it needs at least eight more years of data to understand whether or not the cleanup is working. EPA also concedes that the Lower Hudson River, a 150-mile stretch below the Troy Dam to Manhattan, is not responding to the cleanup as anticipated.

Riverkeeper is deeply concerned that EPA has not adequately recognized the environmental justice implications of the PCB contamination in the Hudson River. Many New Yorkers, especially people in New York City from low-income and minority communities, either rely on subsistence fishing from the Hudson River as an important source of food or would like to do so. As such, EPA should ensure that the communities that are most interested in using the Hudson for subsistence fishing are adequately informed and have a meaningful opportunity to participate in the public comment process for the FYR Report. Unfortunately, EPA has not undertaken sufficient outreach to such communities anywhere along the Hudson River.

Ingestion of contaminated fish from the Hudson River remains a major health concern for New Yorkers, despite longstanding New York Department of Health ("NYSDOH") fish consumption advisories. EPA's own research in 2009 showed that despite state fish consumption advisories, people along the Hudson

continue to eat the fish they catch and bring them home to their families.[1] NYSDOH has also found that awareness of fish consumption advisories among anglers in New York City is about half that of anglers in the Mid and Upper Hudson, with awareness in the Lower Hudson falling between the two.[2] Recent media stories show that this lack of awareness is still problematic. For example, on June 29, 2017, a radio piece on WNYC mistakenly described the fish in New York City waters as "edible, with some exceptions" and dismissed the advisories as, "really a matter of perspective" and "quite subjective."[3] The same day, an article in New York Magazine also downplayed the health risks associated with consuming fish from New York City waterways.[4] In reality, the fish consumption advisories recommend extremely limited consumption generally, and *no* consumption for women under 50 and children under 15, for most fish species from New York City water bodies due to continued PCB contamination.[5]

Despite this significant public health concern, EPA is holding only two public information meetings along the entire 197-mile stretch of the Hudson River Superfund Site, neither of which are located in or near New York City. Moreover, it was clear from the first public information meeting in Poughkeepsie on June 28, 2017 that EPA failed to do sufficient outreach to subsistence fishing communities. When Riverkeeper asked who in the crowd of over 300 people was a subsistence fisher, not a single person raised their hand. The second meeting will take place in Saratoga Springs on July 19, 2017—180 miles from New York City. EPA did not schedule any FYR Report meetings in the low-income and minority communities downriver, which make up much of the subsistence fishing community affected by this toxic contamination.

In other places, EPA is conducting vastly more extensive community outreach at similar Superfund sites. For example, EPA Region 10 has held more than *eighty* community outreach and engagement activities since 2012 regarding the Portland Harbor Superfund Site, which is also contaminated with PCBs.[6] There, EPA identified strategies for reaching out to underrepresented communities in the region, had translators present at meetings, and attended cultural events to promote greater community engagement. Region 10 also studied fish consumption patterns among different ethnic, tribal, and immigrant groups to determine consumption rates and ensure that the risk assessments were contextualized by that consumption.[7]

[5] N.Y. State Dep't of Health, N.Y.C. Region Fish Advisories, (last visited July 6, 2017), https://www.health.ny.gov/environmental/outdoors/fish/health_advisories/regional/new_york_city.htm#table.
[6] U.S. Envtl. Prot. Agency, Region 10, Portland Harbor Cmty. Involvement Plan (2016), at A-2-7, *available at* https://www3.epa.gov/region10/pdf/ph/sitewide/community_involvement_plan_june2016.pdf.
[7] U.S. Envtl. Prot. Agency, Region 10, Record of Decision: Portland Harbor Superfund Site (Jan. 2017) at 35, *avaliable at* https://www3.epa.gov/region10/pdf/ph/sitewide/record-of-decision-jan2017.pdf.

In response to repeated requests from Riverkeeper and others that EPA hold a downriver meeting to provide information on the FYR Report to communities south of Poughkeepsie, and particularly to communities known to consume PCB-contaminated fish regularly or for subsistence, the agency has stated only that implementation of "institutional controls," such as riverside signs warning about consumption risks, is the responsibility of New York State. However, even if New York State is acting concurrently, EPA should still reach out to communities that rely on fish from the Hudson or would like to do so. Under Executive Order 12898, federal agencies are explicitly tasked with "identifying the need for ensuring protection of populations with differential patterns of subsistence consumption of fish and wildlife," and "communicat[ing] to the public the risks of those consumption patterns."[8]

All of your constituents who fish along the Hudson River Superfund Site deserve a meaningful opportunity to participate in the public process for the FYR Report. Riverkeeper respectfully requests that you urge EPA to ensure that the communities most interested in subsistence fishing, particularly those in the New York City area, have a meaningful chance to engage with EPA as the agency decides how to proceed with the PCB cleanup in the Hudson River. Such downriver public information meetings must be convened as soon as possible, and, at the very latest, before the September 1, 2017 deadline for submission of public comments on the FYR Report.

Please feel free to contact our Campaign Advocacy Coordinator, Jeremy Cherson, at (914) 478-4501 ext. 257 or jcherson@riverkeeper.org with any questions. I appreciate your continued involvement in this important issue.

Sincerely,

Richard Webster

Mr. Klawinski,

Please see below a letter from Senators Schumer and Gillibrand requesting your office arrange a New York City meeting on the second five-year review. Given the short time frame remaining in the comment period, we request your office acts as soon as possible to give the public ample time to digest the information before submitting comments.

Please also note that due to the diversity of New York City that your office should arrange for translators and present the information in multiple languages that correspond to the communities most likely to consume fish contaminated with PCBs.

Sincerely,

Jeremy Cherson

RIVERKEEPER
NY's clean water advocate

United States Senate
WASHINGTON, DC 20510

July 18, 2017

Administrator Scott Pruitt
Environmental Protection Agency
1200 Pennsylvania Avenue, NW
Washington, DC 20460

Dear Administrator Pruitt:

We write to urge the Environmental Protection Agency (EPA) to hold a public information meeting in New York City regarding the Proposed Second Five-Year Review Report for the Hudson River Superfund Site. It is crucial that the local community, including those along the Lower Hudson River, have the opportunity to hear directly from the EPA on this proposed report and to have their own voices be heard.

We appreciate that the EPA has already held a public information meeting in Poughkeepsie, and has another meeting planned in Saratoga Springs on July 19. However, we believe it is important that the EPA hold an additional meeting in New York City, as well, to give the maximum number of New Yorkers who live adjacent to the Hudson River an opportunity to participate in the public comment process. There is a significant population of residents in New York City who may have an interest in the status of the cleanup of the Hudson River PCBs Superfund Site and they should have maximum ability to learn about the status of this endeavor and to offer their views on current and future plans in this regard. With Poughkeepsie located more than 80 miles away from New York City, and Saratoga Springs more than 180 miles away, EPA should do more to ensure that potentially interested communities have the opportunity to hear directly from the agency and participate in the public comment process, particularly since some elderly, disabled, low-income, and other residents who have hectic schedules, yet who wish to engage in the process, may have a difficult time attending a meeting so far from home. It is for this reason that we urge the EPA to hold a public information meeting in New York City on this Proposed Second Five-Year Review Report as soon as possible.

Thank you in advance for your consideration of this request. Should you have any additional questions, please do not hesitate to contact our offices.

Sincerely,

Charles E. Schumer
United States Senator

Kirsten Gillibrand
United States Senator

Re: Request for Extension of Public Comment Period for Hudson River PCB Superfund Five Year Review Report

Dear Mr. Klawinski:

We write to request a 90-day extension of the public comment period on the Draft Second Five Year Review (FYR) Report for the Hudson River PCB Superfund Site issued by the Environmental Protection Agency (EPA) Region 2 office on June 1. The current 30-day timeframe is woefully inadequate and would forestall meaningful public participation, which the EPA maintains is an important part of the FYR process.

The extension is necessary for riverfront communities, the public, and state and federal agencies to provide input on the EPA's highly technical review of the protectiveness of the in-river dredging remedy for the Hudson River Superfund Site. The Second FYR is a complex document containing nearly 1,000 pages of detailed information. The public deserves adequate time to understand what the report actually means— especially in regards to the significant public health threats, prohibited access and stymied economic activity this PCB-polluted waterway will inflict on people and communities for generations to come.

This extension is fully within the EPA's authority; in fact, the agency extended the comment period in 2012 for the Hudson's First FYR, a significantly shorter report with much less technical analysis. We urge the EPA to develop a more adequate timeline for this process to allow for effective public participation and foster a clearer understanding of the report's polemical conclusions. At the very least, the EPA should extend the Hudson River PCB Superfund Site Five Year Review Report public comment period until September 29, 2017.

Subject: Fwd: Five Year Review Public Meetings on Hudson River PCB clean up

Gary:

We are getting communications from our members and others complaining about the lack of meetings downstate and in New York City regarding the Five Year Review. We believe that such meetings are essential to ensure full public participation in the Five Year Review process. This is particularly important because awareness of the PCB issue is lower in New York City, the fish advisory is more complex, and there are minority communities that cannot effectively participate in meetings held only in English a long way outside of the City.

We strongly urge EPA to arrange public participation meetings in NYC and to tailor some of the meetings to minorities, who may be most interested in subsistence fishing. I trust that you agree and expect to hear from you soon. However, because of the urgency and importance of this issue we are also going to reach out to federal legislative offices with this request.

I look forward to hearing from you.

Richard Webster

COMMENTS:

GE's 2016 headlines Re: profit moving forward under the Trump administration is "more optimistic." Revenue = $33.1 billion. Don't let GE tell you it can't afford to clean up the Hudson. The lack of environmental responsibility on the part of GE, and the capitulation of the EPA in light of the clear and present dangers (still actively investigated by the State DEC.) need to be addressed. Sure, take time to study what you've done, but move forward with a phase to use suction dredging north of Troy, N.Y. to contain PCBs lifted out of the Hudson. Make GE use the best technology, not the cheapest. They would not survive if they just went cheap — that's Wal-Mart, not GE. Hold them accountable, EPA, -- with a NEW phase, now that they are making more profit using cheaper labor in FL -- a state with fewer regulations. We need closure, but CLEAN CLOSURE with GE.

Re: Comments of Hudson River Environmental Groups and Cleaner Hudson Coalition on the Proposed Second Five-Year Review Report for the Hudson River PCBs Superfund Site

Dear Director Klawinski:

On behalf of Hudson River Fisherman's Association, Hudson River Sloop Clearwater, the Natural Resources Defense Council, Riverkeeper, Inc., Scenic Hudson, Inc., and the Sierra Club Atlantic Chapter we submit the attached detailed comments on the Environmental Protection Agency's Proposed Second Five-Year Review for the Hudson River PCB Superfund Site—one of the largest Superfund Sites in the United States.[1]

Our full comments are attached hereto, but we offer a summary of our primary points below.

Executive Summary

The outcome of the EPA's 5 Year Review for the Hudson River Superfund Site will set an important precedent for other Superfund sites across the nation. EPA's determination that the in-river remedy for the Hudson River Superfund Site "will be protective" of human health and the environment is arbitrary and capricious, and not supported by current data or analysis by independent scientists and the Natural Resource Trustees for the Site, including New York State. EPA acknowledges in its Proposed Second Five Year Review ("FYR") that the in-river remedy is currently "not protective"; this must be the official finding of the final FYR. The FYR should outline next steps toward additional remediation of the Upper Hudson River and commit to a remedial investigation of the Lower Hudson River. A finding by EPA that the remedy is "not protective" will put the entire Hudson River on a speedier path to recovery, and will realize the Superfund statute's goal of protecting the health of the people and wildlife living in and around the River.

Additionally, we emphasize the following:

[1] The Hudson River PCBs Superfund Site is a nearly 200-mile stretch of the Hudson River in eastern New York State from Hudson Falls, New York to the Battery in New York City. It runs adjacent to fourteen counties in New York and two counties in New Jersey. The Site is divided into the Upper Hudson River, which runs from Hudson Falls to the Federal Dam at Troy (a distance of approximately 40 miles), and the Lower Hudson River, which runs from the Federal Dam at Troy to the southern tip of Manhattan at the Battery in New York City (a distance of approximately 150 miles).

- EPA has a non-discretionary duty to ensure Superfund cleanups protect human health and the environment. Demonstrable accomplishment of the remediation goals set forth in the 2002 Record of Decision ("ROD") principally drives whether a remedy is "protective" or "not protective."

- As a threshold matter, EPA's own guidance indicates that "will be protective" is not an appropriate determination for the Hudson River Site. "Will be protective" is only appropriate when a remedy is still "under construction" (i.e., active mobilization or dredging). Because construction of the Hudson River remedy is complete and EPA admits the remedy is currently not protective, the only appropriate protectiveness determination categories pursuant to EPA guidance are "protectiveness deferred" or "not protective."

- Since consumption of fish is the major exposure pathway of concern for both people and wildlife, EPA determined in the ROD that the time to reach target PCB concentrations in fish was the primary factor in selecting the remedy for the Hudson River. It also concluded that remedial alternatives that would take 10-20 years longer to achieve targeted reductions in fish tissue PCB concentrations were "not sufficiently protective." A rapid reduction in PCB concentrations in fish—and therefore a rapid reduction in risks to people and wildlife—was the principle that drove selection of the active dredging remedy.

- Testing undertaken subsequent to the issuance of the ROD found that surface sediment concentrations of PCBs, which drive PCB concentrations in fish, were 2-3 times higher than EPA had previously assumed. After dredging, 3-5 times more residual PCB contamination in surface sediments remained than was expected. Despite this finding, EPA has not reevaluated the appropriateness of the remedy.

- The first interim fish tissue goal for the Site is 0.4 mg/kg of PCBs in species-weighted Upper Hudson average. This goal was projected in the ROD to be reached within 5 years post-dredging. It is nearly certain that the cleanup will not meet the first interim target by 2020; as of 2016, one year after dredging, PCB levels in fish were measured at 1.3 mg/kg—more than 300% greater than the ROD goal. Fish tissue concentrations would have to decline at a rate of over 25% to reach this goal, a near impossibility. Even EPA's exaggerated and unsupported 8% rate of recovery would leave this goal unmet for 10 years beyond the ROD's projection. Independent scientific analyses indicate that more realistic decay rates are 3-5% and, based on this, that the first target goal will likely not be reached for 15-40 years beyond the dates set forth in the ROD. By EPA's own statements in the ROD, such a delay renders the remedy not protective.

- By dismissing the importance of the clearly defined interim fish tissue targets, EPA in effect contends that the cleanup will be protective if it achieves the ROD's numeric remediation goals at some unknown point more than 55 years in the future. This conclusion is unacceptable, as it accepts essentially the same performance standard of the ROD's passive remediation alternatives that were rejected as not sufficiently protective of human health or the environment.

- Because PCB levels continue to present unacceptable risks to human health and the environment, the only measure protecting the public are the institutional controls for the site—specifically, New York State Department of Health's fish consumption advisories. These advisories—which warn women under age fifty and children to eat no fish at all—are ineffective, especially among low-income and minority populations, which are most likely to subsist on Hudson River fish. People all along the Hudson are exposed to toxic levels of General Electric's PCBs, through consumption of fish and other exposure pathways, and will continue to be until the goals of the ROD are reached.

- EPA fails to issue any protectiveness determination at all for the Lower Hudson in its Proposed FYR, and admits that the Lower Hudson is not seeing any detectable reductions in PCB levels as a result of the dredging project as anticipated in the ROD. EPA acknowledges that, rather, localized sediments drive PCB concentrations far more than loads from the Upper Hudson. To ensure that the entirety of the site is protective of human health and the environment, as required by the Superfund Act, EPA must immediately order General Electric to conduct a remedial investigation of the Lower Hudson to evaluate whether additional cleanup is necessary.

Respectfully submitted,

Hayley Carlock, Esq.

USEPA PROPOSED SECOND FIVE YEAR REVIEW OF THE HUDSON RIVER PCBS SUPERFUND SITE

COMMENTS OF HUDSON RIVER FISHERMEN'S ASSOCIATION, HUDSON RIVER SLOOP CLEARWATER, NATURAL RESOURCES DEFENSE COUNCIL, RIVERKEEPER, SCENIC HUDSON AND SIERRA CLUB – ATLANTIC CHAPTER

SEPTEMBER 1, 2017

Table of Contents

I. Introduction

Substantial amounts of General Electric s (GE) toxic polychlorinated biphenyls (PCBs) are still present in the Hudson River—including in sediments, water, and fish—and there is a significant possibility that the river will remain excessively contaminated for decades. Furthermore, EPA s remedy for Hudson River sediment removal (OU2 Remedy) to date is on track to fail to achieve rapid reductions of PCBs within the specific timeframes established to protect human health and the environment. Therefore, the U.S. Environmental Protection Agency (EPA) must issue a not protective determination in the Proposed Second Five Year Review of the Hudson River PCBs Superfund Site (the Proposed Second FYR).[1]

A not protective determination is the only appropriate conclusion consistent with EPA s own Five-Year Review Guidance.[2] In addition, this determination is supported by (1) independent analyses of the Site project data; (2) current and expected environmental conditions as compared to the goals and objectives (remedial action objectives or RAOs) laid out in the 2002 Record of Decision (the 2002 ROD) for the Hudson River PCBs Superfund Site (the Site); and (3) provisions in relevant statutes and regulations, including the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA or the Superfund Act)[3] and the National Contingency Plan,[4] and in operable documents that govern the remediation project.

II. Background

A. General Electric Discharged Toxic PCBs into the Hudson River for Decades, Creating Unacceptable Risks to Human Health and the Environment.

From 1947 to 1977, GE discharged untold amounts of highly toxic PCB waste from two capacitor plants into the waters of the Upper Hudson River near Fort Edward and Glens Falls.[5] PCBs are extremely resistant to decay—destruction by chemical, thermal, and biochemical processes is incredibly difficult and costly. Once in the environment, PCBs travel among soil,

A GE spokesman said the company has not issued an estimate of the volume of PCBs that were discharged to the river.). (Attachment B)

water, and air. Through these exposure pathways, animals and humans bio-accumulate PCB toxins in their bodies, especially in fatty tissues.[6]

The cumulative impacts of PCB contamination on public health and the environmental wellbeing of the riverine ecosystem have been ongoing for 70 years. Since PCBs are bio-accumulative and slow to metabolize, exposure to even low amounts of PCB toxins can cause people and animals to accumulate a much higher body-burden concentration of PCBs than exist in the immediate environment.[7]

For people, PCBs are known carcinogens,[8] endocrine disrupters, and can damage the skin, liver, pancreas, and cardiovascular system. PCBs can also impair the development of the brain and neurological system.[9] Prenatal PCB exposure has been linked to low birth weight babies and, as these children age, to reproductive, developmental, and neurobehavioral disorders that continue for several years.[10] For animals—fish, invertebrates, birds, and mammals—PCB exposure can bring about reproductive failures, developmental impairments, and mortality, causing declines in wildlife populations.[11]

B. The 2002 Record of Decision for the Hudson River Superfund Site Contains Remedial Action Objectives Necessary to Protect Human Health and the Environment.

Because of the threat posed to human health and the environment, in September 1983, much of the Hudson River—nearly 200 miles between Hudson Falls and the Battery in New York City—was recommended for placement on EPA s National Priorities List (NPL). In 1984, a record of decision was issued for the Hudson Superfund Site with an Interim No-Action decision for PCB-contaminated sediment in the river bottom, and a limited in-place capping, containment and monitoring of exposed Remnant Deposits remedy for areas of former river bottom in the Upper Hudson that had been exposed by removal of the Fort Edward Dam.[12] In 1989, as part of the subsequent five-year review of the 1984 record of decision (as required by CERCLA), EPA ordered a reassessment of the no-action remedy. In 2002, the agency issued the another record of decision—the 2002 ROD—for sediment removal (the remedy or remedial action), requiring GE to dredge PCB-contaminated sediment in the most heavily polluted areas of the Upper

Hudson. Contaminated sediments in these hot spots posed a serious, ongoing, and unacceptable risk to human health and the environment.[13]

EPA divided the Hudson River Superfund Site into separate parts or operable units for the purpose of developing a remedial plan for each distinct part. The focus of the Proposed Second FYR is the remedial plan for Operable Unit 2 (OU2), which targets contaminated sediments located in the Upper Hudson River.[14] EPA concluded that active remediation in the Hudson River was necessary to protect the public health or welfare and the environment due to the health hazards associated with human ingestion of fish, as well as the ecological risks associated with ingestion of [Hudson River] fish by birds, fish and mammals. [15]

The 2002 ROD includes five remedial action objectives for the protection of human health and the environment:

1) Reduce the cancer risks and non-cancer health hazards for people eating fish from the Hudson River by reducing the concentration of PCBs in fish;[16]
2) Reduce PCB levels in sediment in order to meet the applicable or relevant and appropriate requirements for surface water;[17]
3) Reduce the inventory (mass) of PCBs in sediments that are or may be bioavailable;[18]
4) Minimize the long-term flow of PCBs that run over the Federal Dam and downstream through the Lower Hudson River;[19] and
5) Reduce the risks to ecological receptors by reducing the concentration of PCBs in fish.[20]

EPA also set specific numeric PCB concentration targets to assure protectiveness, as discussed in detail below.[21]

---

[13] *See generally* U.S. Envtl. Prot. Agency, *Hudson River PCBs Site New York Record of Decision* (Feb. 20, 2002) [hereinafter 2002 ROD] *available at* https://www3.epa.gov/hudson/RecordofDecision-text.pdf.

[14] Other operable units include: Operable Unit 1 (1984 ROD remedy for Remnant Deposits 2-5); Operable Unit 3 (1999 EPA removal of 4,400 tons of contaminated sediments from Rodger s Island); and Operable Unit 4 (yet to be determined remedy for remediation of floodplains). U.S. Envtl. Prot. Agency, *First Five-Year Review Report for Hudson River PCBs Superfund Site*, 1 (Jun. 1, 2012) [hereinafter 2012 FYR] *available at* http://www3.epa.gov/hudson/pdf/Hudson-River-FYR-6-2012.pdf.

[15] 2002 ROD at 49.

[16] *Id.* at 50.

[17] *Id.* at 50-51. For the Hudson River Superfund Site, the federal Applicable Requirements are: 0.5 g/L total PCBs for drinking water (maximum contaminant level under the Safe Drinking Water Act); 1 ng/L for the Ambient Water Quality Criterion; and 0.014 g/L for the criteria continuous concentration Federal Water Quality Criterion in freshwater and 0.03 g/L in saltwater. 2002 ROD at 50-51. The New York State Applicable Requirements are: 0.09 g/L total PCBs for protection of human health and drinking water sources; and 0.12 ng/L for protection of wildlife; 0.001 ng/L for the protection of the health of human consumers of fish. *Id.*

[18] 2002 ROD at 51.

[19] *Id.* at 51.

[20] *Id.* at 50. The selected remedy in the ROD will achieve this in three ways: by (1) a relative reduction in toxicity quotients for the river otter and the mink, measured in the same manner as was done for reduction in risk to human health; (2) reducing the time that it would take . . . to reach the Remediation Goal for protection of ecological receptors, which is a range of PCB concentrations in largemouth bass based on the river otter, and a target range of PCB concentrations in spottail shiner based on the mink ; and (3) [r]educ[ing] PCB loading from the Upper Hudson into the Lower Hudson [to] ultimately reduce the concentrations of PCBs in sediment, water and fish and thereby reduce risk to . . . ecological receptors in the Lower Hudson. *Id.* at 73-75.

[21] *Id.* at 71.

C. EPA Selected the Remedy for the Hudson River Superfund Site Primarily Due to the Expedited Timeframe to Meet Interim and Final Remedial Targets.

In order to accomplish the RAOs, the 2002 ROD evaluated five remedial alternatives—three active remedies and two non-active remedies.[22] The three active remedies involved capping and/or dredging of contaminated sediments, followed by natural attenuation,[23] but only as applied to the northernmost forty miles of the Superfund Site—from the plant sites to the Federal Dam (the Upper Hudson River). The roughly 150 miles of the Hudson Superfund Site below the Federal Dam (the Lower Hudson River) was not . . . identified for active remediation on the assumption that active remediation in the Upper Hudson River would sufficiently reduce[] risks to humans and ecological receptors living in and near the Lower Hudson River. [24]

All three active remedial alternatives outlined in the 2002 ROD divided the Upper Hudson into three distinct sections of unequal length with varying cleanup standards based on the amount of Tri+ PCBs [25] found in surface sediment.[26] The major animating principle behind all three active alternatives was simple: remove or sequester enough PCBs in surface sediments so that PCBs would no longer get into the water column or the food chain where they would harm people and wildlife.[27] By contrast, the non-active remedies included a no action alternative and a monitored natural attenuation (natural attenuation or MNA or MNR) alternative.[28]

The time to reach the interim and final RAOs and targets for fish tissue concentrations were the *primary factor* in EPA s decision to select an active remedy, and reject the non-active alternatives as not sufficiently protective of human health and the environment.[29] To understand and compare the remedial timeframes, EPA relied on computer modeling designed to predict the short-and-long-term concentrations of PCBs in Hudson River sediment, water, and fish.[30] The

---

[22] 2002 ROD at 54-66.
[23] *Id.* at 56-62.
[24] *Id.* at 2.
[25] The remedial alternatives discussed in the ROD target Tri+ PCBs defined as PCB molecules with 3 to 10 chlorine atoms based upon the finding that that the Tri+ PCB concentration ranged from 98 to 100 percent of the total PCB concentration in fish collected. 2002 ROD at 24 n.1. Total PCB levels in the Upper Hudson, however, were roughly 2-4 times higher than the Tri+ PCBs levels. *See* Jay Field et al., *Hudson River Remedy: Unremediated PCBs and the Implications for Restoration* (2011) [hereinafter Unremediated PCBs Trustee Poster] *available at* https://www.fws.gov/northeast/ecologicalservices/HudsonRiver/docs/HRES%20Hudson%20River%20PCBs%20Remedy%20Implications.pdf.
[26] For example, the REM 3/10/Select alternative—which EPA ultimately selected—called for the dredging and removal of contaminated sediments: in areas in River Section 1 with a surface concentration of greater than 3 g/m^2 of Tri+ PCBs; in areas in River Section 2 with a surface concentration more than 10 g/m^2 of Tri+ PCBs; and in select hot spots in River Section 3. 2002 ROD at 58, 94. Similarly, the CAP 3/10/Select remedy called for capping of those same sediments respectively, and the REM 0/0/3 remedy called for removal of contaminated sediments in River Sections 1, 2, and 3 in areas with surface concentrations of Tri+ PCBs of greater than 0 g/m^2, 0 g/m^2, and 3 g/m^2, respectively. *Id.*
[27] *See id.* at 50-51 (discussing remedial action objectives).
[28] The MNA alternative assumed some future control of the PCBs, which at the time were still entering the Hudson ecosystem from the contaminated plant sites (i.e., source control). *Id.* at ii.
[29] *Id.* at 66 (emphasis added).
[30] *Id.*at 26. EPA predictions for PCB fish tissue reduction timeframes were the product of a series of interconnected modeling efforts. The backbone of these efforts was the Upper Hudson River Toxic Chemical Model (HUDTOX), which forecasted PCB concentrations in water and sediment in the Upper Hudson River. U.S. Envtl. Prot. Agency, *Revised Baseline Modeling Report*, ES-2 (Jan. 2000) *available at*

modeling results led EPA to conclude that the No Action and Natural Attenuation remedial alternatives were *not sufficiently protective* of human health and the environment because: (1) the Natural Attenuation alternative would *take at least twenty years longer than the selected remedy* to reach target levels in fish tissue in River Sections 1 and 2; and (2) both non-active alternatives would not sufficiently remedy the unacceptably elevated levels of PCBs in the Upper Hudson as well as the continued degradation of the sediments and surface water quality . . . *for at least several decades longer* than any of the active remedial alternatives. [31] EPA also predicted that it would take *at least 10 additional years* for MNA to reach the 0.2 mg/kg and 0.4 mg/kg PCB target levels, as compared to the active remediation alternatives. [32] In short, EPA determined that the unacceptable risk will continue for many decades without active remediation of the PCB-contaminated sediments and control of the upstream sources. [33]

EPA acknowledged the limited interim protection provided by longstanding New York State Department of Health (NYSDOH) fish consumption advisories.[34] However, the EPA also found that these controls do not protect ecological receptors, and [that] human health risk reduction relies on *knowledge of and voluntary compliance with* the consumption advisories and fishing restrictions, citing evidence that fish consumption advisories are not fully protective of human health due to gaps in compliance. [35] Accordingly, expeditious reduction of PCBs in fish was critical to selection of the remedy and in ensuring the protection of human health and the environment.

D. The OU2 Remedy Must Meet the Specific Targets Set in the 2002 Record of Decision.

In the 2002 ROD, while EPA found all three active remedies to be sufficiently protective, it ultimately selected the REM 3/10/Select alternative. The selected remedy involved removal of sediments with PCB surface concentrations of greater than 3 g/m^2 and10 g/m^2 in River Sections 1 and 2, respectively, and select hot spots in River Section 3.[36]

Although EPA recognized that the REM-0/0/3 Alternative would be *more* protective than the selected REM 3/10/Select option, other considerations including cost and feasibility weighed in favor of the lesser protective 3/10/Select remedy.[37] The fact that the 2002 ROD set a low bar with a remedial goal of 0.05 mg/kg (allowing consumption of one half-pound fish meal a week by men), which will purportedly be met only at some unknown point more than 55 years in the

---

[36] 2002 ROD at 94.

[37] *Id.* at 104.

future, makes it even more important for EPA to ensure that the remedy is on track to meet the interim and final remedial goals that were actually projected in the 2002 ROD.

The 2002 ROD includes the following specific fish tissue and sediment targets:

Fish Tissue Target PCB Concentrations

For human exposure through consumption:

- 0.05 mg/kg in fish fillet for a person eating one-half pound meal per week
- 0.2 mg/kg in fish fillet for a person eating one half-pound meal per month
- 0.4mg/kg in fish fillet for a person eating one-half pound meal every two months

The 2002 ROD provided specific timeframes for achieving these fish tissue targets, although it is worth noting that the document itself is not entirely consistent.[38] The 2002 ROD assumed that fish tissue concentrations would meet the first interim target of 0.4 mg/kg within five years of the completion of dredging and the second interim target of 0.2 mg/kg within sixteen years of the completion of dredging.[39] While EPA did not expect the entire Upper Hudson River to meet the final remedial goal of 0.05 mg/kg within the time period modeled by GE and EPA, it did expect River Section 3 to meet that goal within 43 years of the completion of dredging.[40] Consequently EPA also expected the majority of the Lower Hudson River to meet that goal within the same timeframe due to the lower initial concentration of Site-related PCBs in the Lower Hudson compared to the Upper Hudson. [41]

The short-term targets already allow for some variation from the modeling projections used as the basis for the 2002 ROD targets. According to that modeling, EPA actually anticipated that the REM 3/10/Select Remedy would meet the 0.4 mg/kg fish tissue target within two years of the completion of dredging and the 0.2 mg/kg target within 14 years of the completion of dredging.[42] Furthermore, EPA anticipated that River Section 3 would meet the 0.05 mg/kg target within 41 years of the completion of dredging.

For wildlife exposure through consumption: [43]

- A range of 0.3 to 0.03 mg/kg in largemouth bass (whole body) for river otter
- A range of 0.7 to 0.07 mg/kg in spottail shiner (whole body) for mink

[38] As discussed herein, the 2002 ROD includes timeframes for meeting the short- and long-term targets, as well as model projections. These timelines have slight differences of up to three years. For example, the 2002 ROD expects the remedy to meet the 0.4 mg/kg within five years of the completion of dredging; *id.* at 103, whereas the model projection indicates that the remedy would meet the 0.4 mg/kg target within two years of the completion of dredging. *See* 2002 ROD, Table 11-2. For the purposes of these comments, it is assumed that EPA used 2010 as the year that dredging would be completed in the model projections.
[39] *Id.* at 50.
[40] *Id.* at 103.
[41] *Id.* at 103.
[42] *Id.* at 73.
[43] *Id.* at 50. EPA recalculated the ranges in the Second Five Year Review to 0.2 mg/kg to 0.07 mg/kg for river otter and 0.34 mg/kg to 0.11 mg/kg for mink, both of which lie within the original ranges. 2017 FYR at 65.

EPA expected an active remedy (i.e., one including dredging) to meet the remediation goal range for river otter 30 to 40 years earlier than the No Action or MNA alternatives.[44] Similarly, the agency expected to meet the target range for mink 60 years earlier with an active remedy.[45] Using the dredging period to measure the timelines in the 2002 ROD, the cleanup was expected to achieve the range for river otter within approximately 23 years of the completion of dredging, whereas the range for mink would be met during the dredging period.[46]

Sediment Target PCB Levels

To achieve fish tissue remediation goals, target cleanup levels for sediment were established based on model results relating fish tissue PCB concentrations to sediment PCB concentrations.[47] Under this process, the 2002 ROD set standards for sediment removal including an overall target of removal of approximately 2.65 million cubic yards of PCB-contaminated sediment from the Upper Hudson River, which was estimated to contain 70,000 kg (about 150,000 lbs) of total PCBs or roughly 65% of the then-estimated total PCB mass present in the Upper Hudson River.[48]

River Section 1 (Thompson Island Pool) ~ 6 miles

- 3 g/m2 Tri+ PCBs MPA
- 10 mg/kg Tri+ PCBs in surface sediment (~ 25-30 mg/kg total PCBs in top 12 inches)

River Sections 2 & 3 (multiple reaches/pools) ~ 35 miles

- 10 g/m2 Tri+ PCBs MPA
- 30 mg/kg Tri+ PCBs in surface sediment (~ 60-90 mg/kg total PCBs in top 12 inches)

The sediment removal targets were set on a mass per unit area (MPA) basis predicated on the model-estimated reduction necessary to achieve target fish tissue concentrations.[49] However, the operative fact that will drive protectiveness is the *residual* PCBs left in sediment after dredging, not how much PCB was removed.

III. The Hudson River Five Year Review Process.

EPA is statutorily required to conduct a five-year review of a Superfund site whenever contamination remains on site at a level that does not allow for unlimited use and unrestricted exposure after cleanup. [50] For communities along the nearly 200 miles of the Hudson River contaminated by PCBs, these conditions will exists for the foreseeable future.

[50] 42 U.S.C. 9621(c) (If the President [or his delegate, in this case the EPA Administrator] selects a remedial action that results in any hazardous substances, pollutants, or contaminants remaining at the site, the President shall

Five-year reviews are intended to evaluate the implementation and performance of remedial actions. Through this process, EPA must determine whether the selected remedy is protective of human health and the environment —or, whether the cleanup is working and activities to date will achieve the RAOs. In a five-year review report, EPA should consider the human health and ecological risks as well as the general performance of the selected remedy in order to assess the protectiveness of the cleanup. EPA must then make a protectiveness determination.

Because remedial construction is complete at the Hudson River Superfund Site, as discussed below, EPA must make a site-wide protectiveness determination, which should generally be the same protectiveness determination as the least protective Operable Unit at the site. [51] In addition, because the OU2 remedy here includes the use of institutional controls by way of the NYSDOH fish consumption advisories, EPA must also evaluate the current and long-term effectiveness of the fish consumption advisories and include relevant information about the advisories as part of the protectiveness determination. [52]

In a five-year review, EPA is directed to answer three questions based on and sufficiently supported by data and observations and then make the most appropriate protectiveness determination as guided by the condition of the river and the best available data analysis. The questions and the topics to be included under each question include (but are not limited to) the following:[53]

Question A: Is the remedy functioning as intended by the decision documents? Topics include remedial action performance and monitoring results; system operations/operations and maintenance; costs of system operations/operations and maintenance; opportunities for optimization; early indicators of potential remedy problems; and implementation of institutional controls and other measures.

Question B: Are the exposure assumptions, toxicity data, and Remedial Action Objectives (RAOs) used at the time of the remedy still valid? Topics include changes in exposure pathways; changes in land use; new contaminants and/or contaminant sources; remedy byproducts; changes in standards, newly promulgated standards, and TBCs [To Be Considereds]; changes in toxicity and other contaminant characteristics; expected progress towards meeting RAOs; and risk recalculation/assessment (as applicable).

Question C: Has any other new information come to light that could call into question the protectiveness of the remedy? Topics include ecological risks; natural disaster impacts; and any other information that could call into question the protectiveness of the remedy.

The first five-year review (First FYR) for the Hudson River Superfund Site—which EPA started and completed in only 60 days—was released on June 1, 2012 with a conclusion that the

review such remedial action no less often than each five years after the initiation of such remedial action to assure that human health and the environment are being protected by the remedial action being implemented.).

[51] EPA FYR Guidance Supplement at 2.

[52] *Id.*

[53] EPA FYR Guidance at 3-7 (Exhibit 3-3); *see also id.* at 4-1 to 4-2 (Exhibit 4-1).

OU2 remedial action will be protective. [54] As noted to EPA in comments on the First FYR by some of our organizations,[55] the will be protective statement was erroneous and not supported by a critical review of the project as intended by both statute and EPA s own guidance.[56] While the First FYR acknowledged that high levels of contamination in areas outside of the dredging footprint would delay reaching the 2002 ROD goals within the expected timeframes,[57] EPA offered no recommendations for appropriate action to achieve the protectiveness goals.

Due to EPA s failure to recognize and adaptively manage the predicted shortcomings of the remedy, and following the EPA s de facto approval of the termination of the GE dredging program,[58] some of our organizations filed a petition (the Petition) in December 2015. The Petition demanded that EPA conduct an immediate five year review of the remedy s protectiveness and take all additional necessary actions to ensure human health and environmental RAOs are in fact being achieved.[59] We note that EPA ignored all of the recommendations and concerns expressed in the Petition in the Proposed Second FYR and only gave a cursory written response.[60]

EPA incredibly repeats its erroneous will be protective conclusion in its Proposed Second FYR, issued on June 1, 2017. EPA does so despite acknowledging that remedy is currently not protective of human health and the environment. As discussed further below, the only appropriate determination that EPA can make for the OU2 remedial action in the Proposed Second FYR is not protective.

IV. EPA Has a Duty to Ensure the Remedial Objectives Are Met.

A. EPA Has a Non-Discretionary Duty to Ensure the Remedy Protects Human Health and the Environment.

CERCLA charges EPA with ensuring that toxic pollution in our nation s most contaminated areas is prevented from harming people or the natural environment. Specifically, at Superfund sites like the Hudson River, where EPA identifies pollution that may present an imminent and substantial danger to the public health and welfare, [61] the agency must select an appropriate remedy that will attain a degree of cleanup [that] . . . *at a minimum assures protection of human health and the environment*. [62]

[62] *Id.* at 9621(d) (emphasis added).

This protectiveness standard is further defined through CERCLA and its implementing regulations, which mandate that EPA develop quantifiable cleanup goals designed to eliminate quantifiable risks. In order to identify and implement remedies that are protective of human health and the environment, CERCLA requires that EPA establish site-specific remedial action objectives, including concrete and quantifiable remediation goals.[63] All remedial actions selected by the agency must assure[] protection of human health and the environment. [64] Whether a remedy succeeds or fails under this standard is measured by its ability to meet the remedial action objectives and the remediation goals.[65]

Specifically, for EPA-led cleanups, the agency must establish remedial action objectives specifying . . . remediation goals which establish acceptable exposure levels that are protective of human health and the environment. [66] These exposure levels are numeric, taking into account any federal and state maximums as well as levels associated with quantifiable cancer and non-cancer risks.[67] Indeed, as EPA sediment cleanup guidance provides, it is important that [remedial action objectives], remediation goals, and cleanup levels are based on site-specific data *and are clearly defined*. [68]

These clearly defined goals—memorialized in a record of decision—are the heart of CERCLA. Without them, there is no measurable standard by which EPA can demonstrate satisfaction of its duty to protect human health and the environment—or, alternately, one by which the public can hold the agency accountable.

Quantifiable remediation goals are also the heart of the five-year review process, where EPA . . . is legally responsible for making [a] protectiveness determination for ongoing or completed remedies.[69] The first and most significant question asked in a five-year review is whether the remedy is functioning as intended, determined primarily by whether the relevant performance standards (e.g., cleanup levels, plume containment, pumping rates) are or will likely be met. [70]

[69] EPA FYR Guidance Supplement at 4.
[70] EPA FYR Guidance at 4-1 (Jun. 2001); *id.* at 3-3 (stating quantitative monitoring data are the primary bases of the technical analyses and subsequent protectiveness determination(s)).

In other words, demonstrable accomplishment of the remediation goals contained in the record of decision s remedial objectives principally drives whether a remedy is protective or not protective. [71] Where RAOs and/or remedial goals may not be met, EPA must determine what additional review or action is needed.[72]

In the present case, the threat posed by GE s PCBs in the Hudson River to the health of New Yorkers and the State s environment is clear. As EPA concluded in the 2002 ROD, the significant health and ecological risks associated with the ingestion of PCB-laden fish made active remediation necessary to protect the public health or welfare and the environment. [73] To eliminate this threat, EPA developed specific RAOs and remediation goals to be achieved by the cleanup. EPA s selection of the remedy was premised on its ability to meet these criteria within a reasonably prompt timeframe.[74] The agency now has a duty to ensure that the cleanup achieves those targets in order to protect human health and the environment.

B. EPA Set Clear Goals for Protection of Human Health and the Environment in the 2002 Record of Decision and Cannot Redefine the Measure of Success.

As explained above, setting clear, identifiable remediation goals by which success or failure of a remedy can be measured is at the heart of CERCLA. In the absence of these goals, EPA would be without a measurable standard by which to demonstrate satisfaction of its duty to protect human health and the environment. Moreover, there would be no measurable standard by which EPA and potentially responsible parties—here, GE—could be held accountable.

EPA cannot dismiss the chief remedial goals of the Hudson River remedy—the clearly defined interim fish tissue targets—at this key juncture as unimportant or meaningless. Although the remedy will not be protective until the ultimate fish tissue goal of 0.05 mg/kg is met, the interim targets of 0.4 mg/kg within five years post-dredging and 0.2 mg/kg within 16 years post-dredging are important benchmarks in evaluating whether the remedy is making adequate progress.

Over the course of the Proposed Second FYR process, EPA has repeatedly dismissed the importance of these interim targets. Distressingly, in a 2016 letter to the New York State Department of Environmental Conservation (DEC), EPA implied that numeric goals for PCB levels in fish established in the 2002 ROD are no longer mandatory targets for the cleanup, but merely interim milestones that, once achieved, might allow fish advisories to be relaxed somewhat. [75] EPA also stated that the goals of the selected remedy do not include specific

---

[71] *See* EPA FYR Guidance at 3-4 (review should include [d]ata supporting the effectiveness of the remedy in meeting cleanup levels and remedial action objectives identified in ROD); DOE Groundwater Guidance at 7-10 (The suitability and performance of any completed or ongoing ground water remedial action should be evaluated with respect to the objectives of those actions (e.g., . . . attainment of cleanup levels).). Thus, where quantifiable remediation goals are not met, EPA may not determine that the remedy is protective.

[73] 2002 ROD at 49.

[74] *See id.* at 102-05.

[75] Letter from Judith Enck, U.S. Envtl. Prot. Agency Region 2 Administrator to Basil Seggos, New York Department of Environmental Conservation Commissioner at3 (Dec. 16, 2016) *available at* http://bloximages.chicago2.vip.townnews.com/poststar.com/content/tncms/assets/v3/editorial/c/dd/cdd3e1d5-03bb-5ee6-849e-c7631462ddbf/585c4e9a3209d.pdf.pdf. (Attachment K)

years in which specified PCB levels need to be achieved in fish in order for EPA to deem the remedy protective. [76]

These statements are irresponsible and contradict the fundamental goals of the 2002 ROD, which found consumption of fish [to be] the major pathway of concern for exposure to and harm from PCBs.[77] Indeed, the primary factors EPA used to select an appropriate remedy were its ability to reduce PCB concentrations in fish and [t]he time to reach target PCB concentrations in fish. [78] These remain the touchstones of a successful and protective cleanup today, and to suggest otherwise ignores the current dangers posed by unaddressed PCBs in the Hudson.

While the Proposed Second FYR concludes that the remedies at the Hudson River PCBs Superfund Site *will be protective* of human health and the environment for the Upper Hudson River,[79] it does not provide any specific timeframe in which this will occur. However, the entire point of undergoing active remediation (i.e., dredging) in addition to MNA was to reach more protective fish tissue targets in the short-term.[80] Therefore, EPA s conclusion that the remedy will be protective at some unknown and undetermined point in the future is meaningless because that is the same result that would have occurred if EPA had undertaken *no active remediation at all*.

If EPA does not hold the remedy to the interim fish tissue targets, then it will be impossible to evaluate protectiveness until the MNA period is over, some 55 or more years into the future. This is entirely inconsistent with the purpose and requirements of CERCLA, and with the remedy set forth in the 2002 ROD. As discussed *infra*, it is all but certain that the cleanup will in fact miss the five-year, 0.4 mg/kg fish tissue target. Given the lengthy and uncertain timeline to reach the remedial goal of 0.05 mg/kg, EPA must be willing to measure the effectiveness of the cleanup against the interim targets, and, importantly, admit when the cleanup is falling short.

V. A "Will Be Protective" Determination is Inappropriate for the Hudson River Remedy According to EPA Guidance.

In the Proposed Second FYR, EPA concludes that the remedy will be protective of human health and the environment.[81] Significantly, while the agency claims the remedy will be protective at some unknown point in the future, it admits that the remedy is not yet protective of human health and the environment. [82]

There are five possible conclusions EPA may reach about the protectiveness of the remedy in a five-year review:

1) Protective;
2) Will be protective;

[76] *Id.*
[77] 2002 ROD at 54.
[78] *Id.* at 54, 66.
[79] 2017 FYR at 24 (emphasis added).
[80] 2002 ROD at 104.
[81] 2017 FYR at 8, 71.
[82] *Id.*

3) Short-term protective;
4) Protectiveness cannot be determined (or protectiveness deferred); or
5) Not protective.[83]

Based on the facts and status of the OU2 Remedy, the only protectiveness determinations even potentially available to EPA are (i) not protective or (ii) protectiveness cannot be determined. As discussed further herein, based on the currently available data, EPA must determine that the OU2 remedy is *not protective*.

EPA s Comprehensive Five Year Review Guidance (EPA FYR Guidance) and Guidance Clarifying the Use of Protectiveness Determination for Comprehensive Environmental Response, Compensation and Liability Act Five Year Reviews (EPA Protectiveness Determination Guidance) give clear direction to EPA regional offices in how they are to arrive at five-year review protectiveness determinations. The latter guidance was issued in 2012 specifically to address concerns by the Office of Inspector General that regional offices were not applying protectiveness definitions consistently and were issuing protectiveness determinations that were not fully supported by data.[84]

A. Construction of the OU2 Remedy is Complete.

The status of the remedy is an operating remedial action that has not yet achieved remedial action completion. [85] This initial classification is important as it limits which protectiveness determinations are applicable to the remedy. However, as a preliminary matter, EPA must clarify that the *construction* of the remedial action is in fact complete.[86]

EPA states in its Proposed Second Five Year Review Summary Form that the site has not achieved construction completion,[87] but simply stating this in a single place in the Proposed Second FYR, without any explanation or justification whatsoever, does not make it so. A review of the rest of the Proposed Second FYR report and appendices, the 2002 ROD, and relevant EPA guidance makes it abundantly clear that the OU2 remedy has reached the construction completion milestone.

As EPA repeats numerous times in the Proposed Second FYR, GE completed Phase 2 of the dredging of the Hudson River on October 3, 2015 and backfilling was completed on November

[83] EPA FYR Guidance, at 4-13; *see also* U.S. Envtl. Prot. Agency, *Guidance Clarifying the Use of Protectiveness Determination for Comprehensive Environmental Response, Compensation and Liability Act Five Year Review* (Sept. 13, 2012) [hereinafter EPA Protectiveness Determination Guidance] *available at* https://semspub.epa.gov/work/HQ/174829.pdf. (Attachment L)

[84] *See* U.S. Envtl. Prot. Agency, *Memo Clarifying the Use of Protectiveness Determinations for Comprehensive Environmental Response, Compensation, and Liability Act Five-Year Reviews* at 1 (Sept. 13, 2012) *available at* https://semspub.epa.gov/work/HQ/174829.pdf.

[85] Operating remedial actions are those actions that are ongoing, but where cleanup levels have not yet been achieved. Such actions typically have remedial components requiring several years to reach cleanup levels (e.g., . . . monitored natural attenuation. . . .). 2017 FYR at 4-2.

[86] The OU2 Remedy is clearly not under construction as the physical construction of the remedy, i.e., the in-river dredging and habitat reconstruction, has been completed. *See* EPA FYR Guidance, at 4-2. Additionally, the OU2 Remedy is not a completed remedial action as the cleanup levels have not yet been achieved. *See id.*

[87] 2017 FYR at 14.

5, 2015. Complete demobilization of GE s sediment processing facility—a necessary component to the dredging project—occurred in December 2016, and all other support facilities were demobilized earlier in 2016. The habitat reconstruction portion of the remedial action was completed on August 8, 2016.[88] Therefore, it is plainly clear that the active mobilization component of the remedy—that is, the dredging project—is complete. Only the MNA period and long-term operation, maintenance and monitoring (OM&M) remain.

Throughout the Proposed Second FYR, EPA clearly marks a distinction between the construction phase of the remedy (i.e., dredging and habitat reconstruction) and the subsequent MNA period. For example, in Appendix 8, EPA states that [r]emedial construction included dredging, backfill placement, capping and habitat reconstruction. [89] EPA continues to discuss remedial construction in the past tense throughout this Appendix.[90] Furthermore, EPA states construction of the remedy was scheduled to commence in 2005 and to be conducted over a five-year period. This construction, in addition to monitored natural attenuation of the remaining PCBs, would lead to reductions of PCB concentrations. . . . [91] This statement clearly delineates construction as active dredging not including the subsequent MNA period.

The 2002 ROD is also quite clear with regard to the meaning of construction of the OU2 remedy. The construction period is commensurate with active mobilization for the dredging project. It ends long before the MNA period ends and the ultimate remedial goals are reached. The 2002 ROD discusses specific remedial construction parameters: The construction timeframes represent the estimated time required for mobilization, operation and demobilization of the remedial work, but *do not include the time required for long-term monitoring or OM&M*. [92] When discussing REM 3/10/Select, the remedy ultimately chosen for OU2, EPA states in the 2002 ROD: *After construction is completed*, this alternative relies of institutional controls and MNA until RAOs are achieved. [93] Finally, in the context of the potential for adverse environmental impacts during construction, the 2002 ROD defines construction as dredging and cap placement. [94]

EPA s FYR Guidance explicitly contemplates MNA remedies, like the OU2 remedy, where construction may be complete although cleanup levels have not yet been achieved. The EPA s FYR Guidance consistently defines remedial actions under construction as those where physical construction is not yet complete, as opposed to operating remedial actions, in which construction may be complete but cleanup levels have not yet been achieved.[95]

[92] 2002 ROD, at 56 (emphasis added)
[93] *Id.* at 60 (emphasis added). *See also id.* at 81 (After construction of the remedy is completed, the natural attenuation process would provide additional reductions.).
[94] 2002 ROD at 85.
[95] EPA FYR Guidance at 4-2 (MNA remedies cited as specific example); *see also* U.S. Envtl. Prot. Agency, *Close Out Procedures for National Priorities List Sites*, 1-2 (May 2011) [hereinafter EPA NPL Close Out Procedures] *available at* https://semspub.epa.gov/work/HQ/176076.pdf.

EPA does mention, in other areas of the Proposed Second FYR, that it will not consider the OU2 *remedy* to be complete until the natural attenuation component has also been completed and the RAOs have been achieved.[96] EPA is correct that remedial action completion will not occur until the MNA period has ended and all cleanup levels have been reached.[97] However, completion of the remedial action is an entirely distinct milestone from construction completion. [98] It is the completion of *construction* that is relevant in determining which protectiveness determinations are available to EPA, as discussed above.

Therefore, EPA cannot credibly argue that construction of the OU2 remedy is ongoing, and any assertions to that effect are arbitrary and capricious.

B. The Only Protectiveness Determinations Available for the OU2 Remedy are "Not Protective" and "Protectiveness Deferred."

EPA s determination that the remedy will be protective is inappropriate for the remedy according to the agency s FYR Guidance and Protectiveness Determination Guidance. According to the Protectiveness Determination Guidance, a will be protective determination is only appropriate when remedial construction activities are ongoing but the remedy is anticipated to be protective upon completion and no remedy implementation or performance issues have been identified.[99] Therefore, will be protective is not an available option for the OU2 remedy because, as explained above, construction of the remedy is complete—the physical and engineering components of the remedial action were completed in 2015 and 2016, respectively. Moreover, regardless of the status of the construction of the remedy, exposures are not currently under control and unacceptable risks are occurring, as explained further throughout these comments.

EPA admits in the Proposed Second FYR that the remedy is not currently protective of human health and the environment.[100] The human and ecological risks remain well above EPA s acceptable risk range,[101] and the institutional controls (fish consumption advisories) are not even close to completely effective in preventing actual exposures to these unacceptable risks.[102]

For all of these reasons, EPA s determination that the remedy will be protective is inconsistent with agency guidance and inappropriate for the OU2 remedy.[103] The only protectiveness

[98] EPA FYR Guidance at 4-2.
[99] EPA Protectiveness Determination Guidance at 3.
[100] 2017 FYR at 8.
[101] The risk-based RAO for the protection of human health is 0.05 mg/kg in fish fillet based on cancer and non-cancer hazard indices for the RME adult fish consumption rate of one half-pound meal per week. Current average fish tissue levels are many times that amount (1.3 mg/kg in 2016). 2017 FYR at 17.
[102] *See id.* at 62 (EPA acknowledged in the 2002 ROD that the consumption advisories are not fully effective in preventing or limiting fish consumption.).
[103] Indeed, as DEC pointed out in its December 2016 Recommendations to EPA for the Five Year Review Report for Hudson River PCBs Site, EPA s 2012 Five Year Review determination that the remedy will be protective may not have been in compliance with EPA guidance because EPA acknowledged in 2012 that human and ecological risks were not under control and that the risks remained unacceptable. *See* New York State Dep t of Envtl. Conservation, *Recommendations to EPA for the 'Five Year Review Report' for Hudson River PCBs Site* at 18-

determinations potentially available to EPA in the Proposed Second FYR are not protective and protectiveness deferred. As discussed throughout this comment, based on current data, EPA must find the remedy not protective.

VI. Current Data Indicate the Remedy is Not Protective of Human Health and the Environment.

A. Fish Tissue PCB Concentrations

1. The 2002 ROD Established Clear Interim Remedial Targets for Fish Tissue Concentrations.

The remedial objective in the 2002 ROD specific to fish tissue concentrations and human health is to [r]educe the cancer risks and non-cancer health hazards for people eating fish from the Hudson River by reducing the concentration of PCBs in fish. [104] In furtherance of this RAO, the 2002 ROD contains three target fish tissue concentrations for the cleanup: 0.4 mg/kg (safe to consume one half-pound fish meal every two months); 0.2 mg/kg (safe to consume one half-pound fish meal per month); and 0.05 mg/kg (safe to consume one half-pound meal every week). [105] The final target of 0.05 mg/kg is the remedial goal of the cleanup for the protection of human health. [106]

As discussed above, EPA evaluated five remedial alternatives in the 2002 ROD. In doing so, EPA stated that [t]he time to reach target PCB concentrations in fish was a *primary factor* in comparing remedial alternatives. [107] Alternatives that included active remediation (i.e., dredging or capping) met the interim and final targets more quickly than the No Action and MNA alternatives. [108] The table below, reproduced from the 2002 ROD, [109] illustrates the differences among the alternatives in meeting the targets.

TABLE 1

Year to Reach Human Health Risk-based PCB Concentrations in Species-weighted Fish Fillet Upper Hudson River[1]

Alternative	Remediation Goal (0.05 mg/kg)	0.2 mg/kg	0.4 mg/kg
No Action[2]	> 2067	> 2067	> 2067
MNA[3]	> 2067	2035 to > 2067	2024 to > 2067
CAP-3/10/Select	> 2067	2024	2013
REM-3/10/Select	> 2067	2024	2012
REM-0/0/3	> 2067	2018	2010

1 Upper Hudson River average is weighted by river section length. River Section 1: 6.3 miles = 15.4%; River Sect ion 2: 5.1 miles = 12 .5%; and River Sect ion 3: 29 .5 miles = 72 .1%.

2 > 2067 means that the level will not be achieved within the model forecast period (*i.e.*, by 2067).

3 Higher value is upper bound.

The modeling for the 2002 ROD projected that the interim targets would be met, on a river section average basis, in 2012 and 2024, respectively.[110] Considering that the dredging was not completed until 2015, it stands to reason that the remedy would now be projected to meet the 0.4 mg/kg by 2017 (within two years of the completion of dredging) and the interim target of 0.2 mg/kg by 2029 (within 14 years of the completion of dredging). The interim targets in the 2002 ROD, which expected fish recovery to occur more slowly than model projections, would now allow for the 0.04 mg/kg target to be met by 2020 (within five years of the completion of dredging) and the 0.2 mg/kg target by 2031 (within 16 years of the completion of dredging).[111]

As discussed above, the time to reach the interim and final targets was a key component in EPA s selection of the remedy. Based on EPA s own rationale for selecting an active remedy, it is clear that delays of ten or more years in reaching the interim and final targets are not protective of human health.

2. Fish Tissue Concentrations Have Declined Since the Dredging Period, but There is Variation Among Species and Location.

It is undisputed that current fish tissue concentrations in the Upper Hudson River threaten both human health and the environment.[112] Although still hazardous, limited post-dredging data

[110] *See* 2002 ROD at Table 11-2.
[111] *See id.* at 103.
[112] *See, e.g.,* 2017 FYR at 71 (stating that as of the date of this five-year review, EPA recognizes the remedy at OU2 to be not yet protective of human health and the environment.); DEC Report at 28 (stating that the current fish

indicates that fish tissue concentrations in the Upper Hudson River have declined since the dredging period.[113] According to EPA, the 2016 data suggests that fish have begun to recover from dredging impacts and are generally back to pre-dredging levels.[114] Specifically, in 2009, prior to the start of dredging, the species weighted, wet weight average was 1.4 mg/kg.[115] In 2016, one year after the completion of dredging, the species weighted, wet weight average was 1.3 mg/kg.[116] EPA also claims that certain species are at or near the 0.4 mg/kg target in the Upper Hudson River, including largemouth bass and yellow perch.[117]

The Hudson River Foundation s (HRF) June 2017 Report, *An Independent Evaluation of the PCB Dredging Program on the Upper Hudson and Lower Hudson River*, also indicates that fish tissue concentrations in the Upper Hudson River have declined since the dredging period.[118] However, HRF found that those declines vary by location and by species. For example, in Thompson Island Pool in River Section 1, post-dredging TPCB concentrations in pumpkinseed and small forage fish were three to six times lower than observed pre-dredging levels.[119] Further downstream, the results are mixed.[120] At sampling locations in River Sections 2 and 3, concentrations in pumpkinseed were only two times lower than pre-dredging levels, and concentrations in small forage fish had declined very little, if at all.[121] In fact, at some locations, concentrations in small forage fish were *higher* than pre-dredging levels.[122]

This variability shows that fish tissue concentrations are closely tied to localized remedial activity and sediment contamination in the Upper Hudson River. HRF concluded that dredging in the Upper Hudson River was most effective in Thompson Island Pool, where a significant amount of sediment removal occurred.[123] The lack of response in small forage fish downstream reflects the linkages of TPCB concentrations in forage fish to localized sediment contamination levels and the limited areas that were targeted for dredging between Schuylerville and Waterford.[124] HRF s analysis should prompt EPA to reevaluate the relationship between fish tissue concentrations and localized sediments in the Upper Hudson River.

In short, while certain fish tissue concentrations have declined to some extent in the Upper Hudson River, the variation among species and locations requires additional investigation.

---

tissue concentrations in the Upper Hudson River continue to result in exposures to both human and ecological receptors which are above EPA s acceptable risk range.); Hudson River Found., *An Independent Evaluation of the PCB Dredging Program on the Upper Hudson and Lower Hudson River*, 17 (June 2017) [hereinafter HRF Report] *available at* http://www.hudsonriver.org/download/2017-06-01Report-HRFDredgingProgramEvaluationFinal.pdf (stating that [b]ased on the 2016 post-dredging monitoring, TPCB concentrations in fish throughout the Upper and Lower Hudson remain above interim target levels and remediation goal specified in the ROD.).(Attachment N)

3. Although There is a Significant Amount of Uncertainty and Variability Involved in Fish Tissue Recovery Rates, it is Clear That EPA Has Overstated the Recovery Rate.

At the August 9, 2017 Five Year Review Team Meeting, EPA stated that it continues to expect fish tissue recovery rates to be approximately 8% per year. However, as further detailed in an independent expert analysis, *Hudson River PCBs Site Proposed Second Five Year Review – Technical Review* prepared by S.S. Papadopulos & Associates, Inc. (SSPA), there is considerable uncertainty and variability in fish tissue recovery rates.[125] EPA s conversion of Aroclor data into homologue equivalent data is among the sources of uncertainty introduced.[126] Specifically, the method used for Aroclor data (M8082) is known to result in inaccuracy and increased uncertainty; the process of converting Aroclor data to homologue equivalent data involves a large amount of uncertainty that EPA failed to take into account; and extrapolating from one data set to another added even more uncertainty.[127] The uncertainty involved—and unaccounted for—in the data conversion process is particularly troubling, as EPA used those data to support an 8% recovery rate in fish tissue.[128]

EPA s inconsistent use of rib-out data is also problematic. EPA stated that rib-out data could be used [i]f the margin of error between rib-on and rib-off measurements [was] less than 20% of the average of lipid normalized PCB concentrations with a 95% confidence level .[129] Consequently, rib-out data were excluded from wet weight trends, as they differed by a factor of two or more, but the data were included in lipid normalized trends, as they differed by less than 20%.[130] However, the difference between individual paired rib-in and rib-out samples could be much greater—up to 75%.[131] Although there were significant discrepancies among some individual paired samples, EPA still utilized the suspect 2007 and 2008 data in calculating an 8% average recovery rate.[132]

In addition to these uncertainties, SSPA determined that fish tissue recovery rates are highly variable and misleading in the context of a protectiveness determination.[133] SSPA plotted several variations to demonstrate the uncertainty in EPA s anticipated recovery rate of 8%.[134] The variations on the use of rib-out data or Aroclor based measurement data show the potential for significantly different fish tissue recovery rates.[135] Those different rates, which ranged from 4% to 8%, could add decades onto recovery times.[136] For example, using the current average fish tissue concentration of 1.3 mg/kg, and assuming a 4% recovery rate, fish in the Upper Hudson River would not reach the 0.4 mg/kg five-year target for 27 years and the 0.2 mg/kg 16-year

[125] *See generally* S.S. Papadopulos & Associates, Inc., *Hudson River PCBs Site Proposed Second Five Year Review – Technical Review* (August 2017) (Attachment O) [hereinafter SSPA].

[136] *See* SSPA at 18 (Table 3).

target for 43 years.[137] Even if EPA s unsupported and optimistic recovery rate of 8% actually occurs, it would take 15 years to get below five-year target.[138]

SSPA made several significant observations regarding the uncertainty and variability as it relates to EPA s anticipated 8% recovery rate:

> The average 8% rate is shown to be uncertain when it is not reproducible with slight variations in data inclusion. In fact, the variations consistently produced average rates of recovery lower than the rate calculated using EPA s approach. *EPA's approach therefore results in recovery rates that are biased high*; the EPA rate is at the fastest end of the range of recovery rates found by applying slight changes to method.
>
> Furthermore, □ the individual rates of recovery vary drastically by species and river section □. Importantly, the use of an average rate, while useful in representing the central tendency of recovery rates, *is deceptive in determining EPA's protectiveness statement for the Site*, because those fish populations with slow recovery rates or slightly increasing trends have half-lives several decades longer than the 8 years suggested by the 8% rate. These populations will continue to be an exposure risk for human health beyond the timeframe suggested by the 2017 Proposed FYR.[139]

In short, EPA s conclusion that the remedy will be protective based on an 8% recovery rate fails to account for significant uncertainty and variability. Furthermore, SSPA s analysis shows that EPA s anticipated recovery rate is overly optimistic, and that slower recovery rates will add decades to the 2002 ROD timeframes.

4. <u>The Cleanup is Not on Track to Meet the First Interim Target Within Five Years of Completion of Dredging.</u>

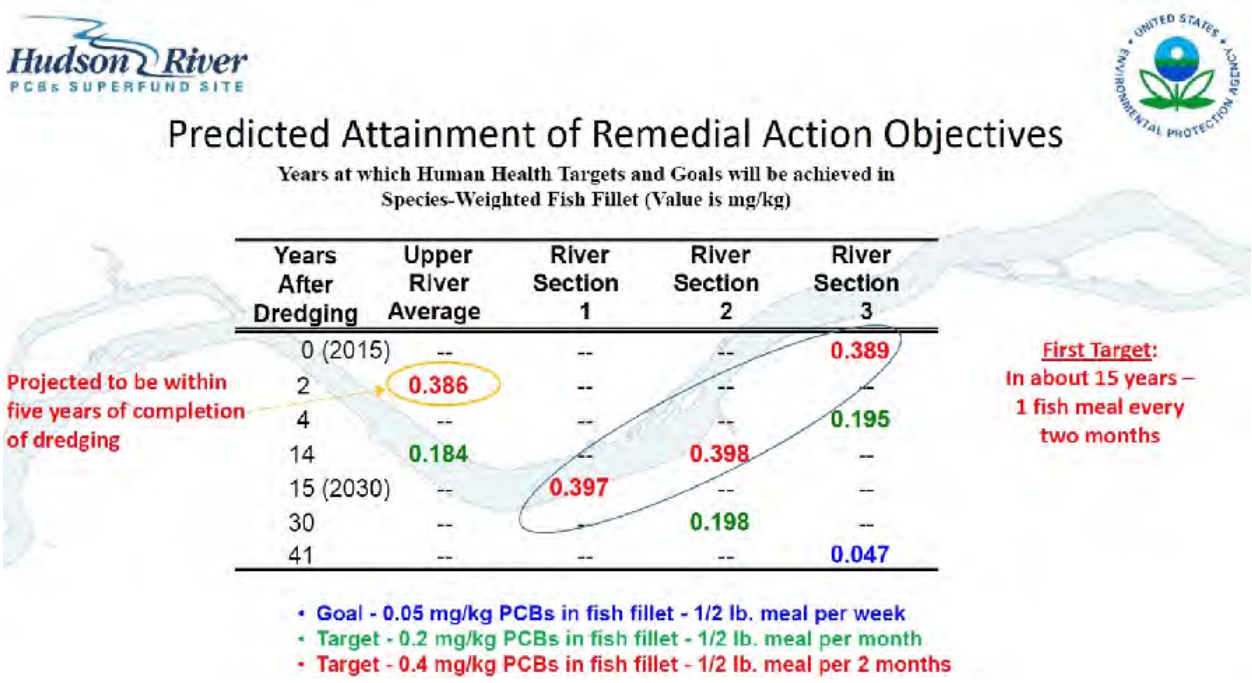
EPA recognizes that the remedy is not yet protective of human health and the environment in the Upper Hudson River, and points to the fact that the 2002 ROD did not anticipate the remedy to be protective by this time.[140] While it is true that the 2002 ROD did not expect the remedy to be protective two years after the completion of dredging, EPA ignores what the 2002 ROD *did* expect in the near term—that within five years of dredging, average fish tissue concentrations would be at or below 0.4 mg/kg. While more data is necessary to fully understand the timeline for reaching the interim and final targets, the cleanup will *not* meet the five-year target of 0.4 mg/kg for more than 15 years after the completion of dredging if its current expectations about recovery rate are correct.

According to EPA, the 2016 data indicates that the species weighted, wet weight fish tissue concentration in the Upper Hudson River is 1.3 mg/kg. With fish tissue concentrations at that

[137] *Id.*
[138] *Id.*
[139] *Id.* at 12-13 (emphases added).
[140] 2017 FYR at 8 (stating that [a]s expected in the [ROD], average PCB concentrations in fish in the Upper Hudson are declining but have not yet reached protective levels.).

level, concentrations would have to decline at a very high rate of over 25% in order to meet the 0.4 mg/kg goal within five years of the completion of dredging, or by 2020, which is all but impossible. Even assuming an 8% decay rate, which is optimistic, the Upper Hudson Average would miss the 2020 target by more than ten years. As discussed *supra*, EPA has already determined that delays of ten years or more in meeting the interim and final targets are unacceptable. Because the data show that the recovery will occur at a rate that the 2002 ROD found was not protective in the context of other remedial alternatives, EPA has no basis whatsoever to find that the remedy will be protective for the Upper Hudson.

At the July 20, 2017 Community Advisory Group meeting, EPA itself admitted that the cleanup will not meet the five-year target on an Upper Hudson Average basis.[141] However, EPA has not made that clear in the Proposed Second FYR or in its public presentations to date. Rather, EPA created a PowerPoint slide based on Table 11-2 from the 2002 ROD, which shows the specific years in which the cleanup was expected to meet the interim and final remedial goals on an Upper Hudson Average and River Section basis.[142] The slide from EPA s presentation to the CAG is reproduced below.



EPA s use of this slide is misleading. The information is merely a recitation of the 2002 ROD modeling, but EPA uses it to suggest that the First Target is 15 years from the date of completion of dredging, not five years, as is actually the case. Moreover, the slide continues to suggest that the Upper Hudson Average will meet the 0.4 mg/kg target within five years of dredging (potentially even within two years), even though it will almost certainly miss that target. Finally, if the Upper Hudson Average will not meet the 0.4 mg/kg target until 2031 (as is

[141] EPA walked back this admission at the August 9, 2017 Public Information Meeting in NYC, suggesting that the target may not be met for seven years or more, and again at the August 16, 2017 Five Year Review Team meeting, insisting that it did not know whether the target would be met within five years.
[142] *See* 2002 ROD Table 11-2 at p.3 of 4.

the case with current conditions, assuming an 8% decay rate) one or more river sections will lag behind, meaning that in about 15 years, it is very unlikely that it will be safe to eat one fish meal every two months from each of the river sections.[143]

Although there is a significant amount of uncertainty and variability regarding decay rates, EPA must recognize that the cleanup will not meet the five-year target as set out in the 2002 ROD. In fact, it is likely that meeting the 0.4 mg/kg interim target will occur at a rate that EPA already determined was not protective for the other remedial alternatives considered in the 2002 ROD. Therefore, EPA should find that the remedy is a not protective and require GE to undertake for further investigation and remediation to get the cleanup back on track.

5. EPA Lacks Necessary Information to Make Long Term Predictions About Whether the Remedy Will Be Protective in the Future.

EPA asserts that it does not have sufficient data to predict future trends in fish tissue concentrations.[144] In fact, EPA repeatedly states that it needs *at least* eight more years of data to draw statistically based conclusion about trends with a high degree of confidence. [145] However, despite lacking key information necessary to evaluate the effectiveness of the cleanup, EPA insists that declines in fish tissue concentrations are generally consistent with ROD predictions and that the system is responding as anticipated. [146] In fact, the absolute level of PCBs in fish in the Upper Hudson is much higher than EPA anticipated at two years post-dredging, and the rates of decline observed are lower than EPA predicted. EPA cannot have it both ways. It should either make no prediction about the future if it thinks uncertainty is too high, or it should find that the first target will not be met if its current expectation about the rate of decline in fish tissue concentrations is correct. Both approaches lead to the same finding—that the remedy is not protective.

Essentially, EPA contends that the cleanup is consistent with the 2002 ROD as long as it will be protective at some unknown point in the future, following an undefined period of monitored natural attenuation.[147] EPA either cannot or will not provide specific timeframes in the Proposed Second FYR for when it expects the cleanup to meet the 2002 ROD targets.[148] Instead, EPA merely states that it does not expect to meet the remedial goal of 0.05 mg/kg for decades, and that it expects to meet the interim targets of 0.4 and 0.2 much sooner. [149]

EPA s statements in the Proposed Second FYR regarding the 2002 ROD expectations are inconsistent with its statements at recent public events. For example, in the Proposed Second

[143] *See id.* (showing that River Sections 1 and 2 were not expected to meet the 0.4 mg/kg target until 12 to 13 years after the Upper River Average).
[144] *See e.g.*, 2017 FYR at 5 (stating that [f]ish, sediment, and water data at this early time are not sufficient to identify post-dredging trends with a high degree of confidence.).
[145] *Id.* at 6; *see also id.* at 33, 69, 70; *id.* App x 3 at 1-2; *id.* App x 3 at 6-2, 6-3.
[146] 2017 FYR at 58.
[147] *See id.* at 8 (stating that EPA expects that continued natural attenuation following the completion of dredging will achieve the long term remediation goal . . . . As EPA indicated in the [ROD], EPA believes it likely that improvement will occur gradually over several decades at least.); *see also id*. at 24.
[148] *See* 2017 FYR at 58 (stating that [a]s additional post dredging data are collected, EPA will be able to further assess the specific timeframes to achieve the 0.2 mg/kg and 0.4 mg/kg target levels.).
[149] 2017 FYR at 33.

FYR, EPA asserts that declines in tissue concentrations consistent with 2002 ROD predictions. Although further monitoring will be required to verify that RAOs are being achieved, the lines of evidence to this point indicate that the system is responding as anticipated and that target levels will be achieved within the timeframes predicted in the ROD. [150] However, as discussed above, EPA admitted at the July 20, 2017 CAG meeting that the cleanup will miss the five-year target.

In sum, fish tissue concentrations throughout the Hudson River Superfund Site continue to pose a threat to human health and the environment. In the Upper Hudson River, evidence suggests that declines in fish tissue concentrations associated with dredging vary by species and location. Furthermore, there is considerable uncertainty and variability with regard to fish tissue recovery rates. However, it is nearly certain that the cleanup will miss the five-year interim target of 0.4 mg/kg. Finally, EPA admits that it cannot predict when fish tissue concentrations will meet the 2002 ROD targets with any confidence. Therefore, EPA cannot support its finding that the cleanup will be protective of human health.

6. The Lack of Response in Fish Tissue Concentrations in the Lower Hudson River Demonstrates the Need for a Full Remedial Investigation and Feasibility Study.

EPA expressly admits that fish tissue concentrations in the Lower Hudson River are not responding as anticipated. EPA recognizes that it is clear that [t]he rate of decline of fish tissue PCB concentrations generally decreases with distance downstream. As a result, there is a decrease in the correlation between fish PCB concentrations in the Upper Hudson River and Lower Hudson River with distance downstream. [151] EPA interprets the data to show that the Lower Hudson River recovers more slowly than the Upper Hudson under MNA. [152] In fact, the data that EPA relies on in the Proposed Second FYR show that decay rates during the MNA period from Poughkeepsie/Kingston downstream are not statistically different from zero. [153]

TABLE 2

Decay Rates During the MNA Period According to EPA's Proposed Second FYR[154]

Monitoring Location	Wet-Weight	Lipid Normalized
Upper Hudson	16%	8%
Albany/Troy (RM152)	16%	10%
Catskill (RM113)	11%	3%
Poughkeepsie/Kingston (RM90)	8%	~0%
Newburgh (RM50)	1%	~0%

Rates of decay in the Lower Hudson River also vary by species. While EPA claims that several species are at or near the 0.4 mg/kg or 0.2 mg/kg targets in the Lower Hudson River, and that

[150] 2017 FYR App x 3 at 7-2.
[151] 2017 FYR at 6, 33, 57, 70; *id.* App x 3 at 7-1; *id.* App x 3 at 4-5.
[152] *Id.* App x 3 at 4-7.
[153] 2017 FYR App x 3 at 7-1.
[154] 2017 FYR App x 3 at 4-5, 4-6

yellow perch are at the 0.05 mg/kg target, other species are recovering at a slower rate. In fact, EPA admits that decay rate estimates are variable across species and locations, with the brown bullhead demonstrating the slowest recovery . . . . [155]

EPA attributes the differences between the Upper Hudson and Lower Hudson to a number of potential factors, including the fate and transport of PCBs in the Lower Hudson River.[156] It is likely true that fate and transport in the tidal Lower Hudson River differs from the Upper Hudson River. According to HRF, the complexity of sediment transport in the Lower Hudson contributes to the lack of response in fish to the upriver dredging.[157] As HRF explains, [t]he continuous interaction of the overlying water with sediments (through setting, resuspension, and pore water exchange) and the large capacity of the sediments to sorb PCBs work together to dampen the PCB responses downstream and to greatly extend PCB response times to changes in Upper Hudson PCB loads. [158] Significantly, HRF concludes that the Lower Hudson River appear[s] to be responding very slowly to changes in PCB inputs from the Upper Hudson. [159]

DEC has also expressed concerns about the relationship between localized sediments and fish tissue concentrations in the Lower Hudson. Specifically, DEC asserts that the degree to which local sediments influence fish PCB concentrations is greater than thought at the time of remedy selection. As a result, there will be little additional improvement in fish PCB concentrations in the lower Hudson, particularly south of Albany, as a result of the dredging. [160] Ultimately, the issues raised by HRF and DEC regarding fate and transport of PCBs in the Lower Hudson River and the degree to which localized sediments impact fish tissue concentrations support the need for a full investigation.

EPA also speculates that other sources of PCB contamination may be responsible for the slow recovery in the Lower Hudson River. Although other sources of PCBs do exist—namely ARCO in Hastings and BICC Cables in Yonkers—EPA has stated in public meetings that it is undisputed that GE is the primary contributor. As such, the mere presence of other sources of PCB contamination should not deter EPA from ordering GE to undertake a full remedial investigation and feasibility study in the Lower Hudson River.

Despite the slow response thus far, EPA still maintains that the PCB load reduction from the Upper Hudson River will benefit the Lower Hudson River.[161] However, it is not clear how quickly that will occur, if at all. HRF anticipates that it would take a decade or more to see appreciable change in PCB water column, sediment, and fish concentrations at many locations in the Lower Hudson. [162] DEC takes an even less optimistic view:

---

[155] *Id.* at 4-11; *see also, id*. at 4-12 (stating that declines in PCB concentrations are occurring more rapidly in the Upper Hudson and less rapidly in the Lower Hudson with estimate rates not statistically different from zero for several species at RM113, RM90 and RM50).

[157] *Id.* at i.
[158] *Id.* at 16.
[159] *Id.* at 17.
[160] DEC Report at 37.
[161] 2017 FYR at 57.
[162] HRF Report at iii.

> Insufficient data are available in the lower Hudson to answer the question as to the magnitude of the delay in reaching the Remediation Goal of 0.05 ppm PCB in fish, However, given the limited impact of the remedy to date on fish in the Lower Hudson below Albany it is not anticipated that there will be further improvements in fish PCB in this area as a result of the dredging. Currently available fish PCB concentrations indicate ongoing exposures present unacceptable human health and ecological risk.[163]

DEC concludes that the anticipated reductions in fish PCB concentrations in the lower Hudson, as a result of the remedial work in the upper Hudson, will likely not occur as anticipated in the ROD.[164]

Furthermore, the National Oceanic and Atmospheric Administration (NOAA) recently published a peer-reviewed study that used model emulation to predict fish tissue concentrations in the Lower Hudson River based on post-ROD data.[165] The data that NOAA relied on showed that surface sediment concentrations in the Upper Hudson River were higher than expected.[166] In addition, NOAA determined that a 3% sediment recovery rate was more in line with the data than the 8% recovery rate used in the modeling for the 2002 ROD.[167] By considering these different inputs, NOAA s analysis indicates that EPA may have greatly underestimated the timeframes for fish recovery in the Lower Hudson River, and that it could take decades longer than anticipated to meet the interim targets south of the Troy Dam.[168] To illustrate this point, NOAA includes specific projections for white perch at RM 152.[169] Using updated sediment concentrations and assuming a 3% decay rate, white perch would not meet the 0.4 mg/kg and 0.2 mg/kg targets for 44 and 67 years, respectively.[170]

Even with skepticism and disagreement from NOAA, DEC, and HRF, EPA maintains that the slow response in the Lower Hudson is consistent with the 2002 ROD expectations.[171] This is despite its finding that the model used for the 2002 ROD underpredicted fish tissue levels in the Lower Hudson.[172] Moreover, EPA makes several vague and seemingly inconsistent statements about the remedy. For example, EPA contends that the 2002 ROD did not predict significant impacts from dredging, but nevertheless predicted [s]ome improvements as a

---

[163] DEC Report at 26.

result of the remedy.[173] Unsurprisingly, EPA claims that [b]oth predictions are consistent with observations. [174] However, EPA also admits that observations support a lack of significant response between Upper Hudson processes, e.g., dredging releases, and Lower Hudson impacts. [175] Regardless of EPA s current characterization of the 2002 ROD expectations, the lack of any significant response suggests that EPA was incorrect in assuming that the Lower Hudson River would meet the final remedial goal of 0.05 mg/kg in the same timeframe as River Section 3.[176]

In sum, the Lower Hudson River is responding very slowly to the cleanup, if at all. Evidence suggests that there is a disconnect between the remedial activities in the Upper Hudson River and the response in the Lower Hudson River. Therefore, EPA should require GE to conduct a full remedial investigation and feasibility study to address the ongoing PCB contamination in the Lower Hudson River.

B. Sediment Contamination

The 2002 ROD acknowledged that [o]nce introduced to the river, PCBs adhere to the sediments. Physical, chemical, and biological release mechanisms allow PCBs in the sediment to be available for redistribution and to be a source of PCB contamination to the water column. Sediments would continue to release contamination to the water column and to biota, through aquatic and benthic food chains, *unless they are managed or remediated*. [177] Consequently, to address the threat to human health and the environment posed by PCB contaminated sediments, the 2002 ROD included the following remediation objectives: [r]educe PCB levels in sediments in order to reduce PCB concentrations in river (surface) water that are above applicable or relevant and appropriate requirements, [178] and [r]educe the inventory (mass) of PCBs in sediments that are or may be bioavailable in order to ultimately reduce PCB levels in fish and the associated risks to human health and the environment.[179] So, the mass of PCBs that may become bioavailable are closely related to the concentration of PCBs in surface sediments. [180] Consequently, the remedy focused on removing PCBs from targeted (dredged) areas, with focus on surface sediment concentrations as the main mechanism through which PCB concentrations in fish would be influenced.

The 2002 ROD thus required [r]emoval of all PCB-contaminated sediments within areas targeted for remediation [namely, hot spots] with an anticipated residual of approximately 1 mg/kg Tri+ PCBs, as well as the [u]se of environmental dredging techniques to minimize and control resuspension of sediments during dredging. [181] To this end, the 2002 ROD estimated [that the] volume of sediments to be removed is 2.65 million cubic yards, which is estimated to

[181] *Id.* at ii-iii (emphasis added).

contain 70,000 kg (about 150,000 lbs) of total PCBs. [182] This remediation target for the chosen alternative, REM 3/10/Select, was broken down by River Section in the 2002 ROD Table 13-1, with estimated removals of 36,000 kg total PCBs for River Section 1; 24,300 kg total PCBs for River Section 2; and 9,500 kg PCBs total for River Section 3.[183]

During Phase 1 of the implementation of the selected remedy, REM 3/10/Select, EPA discovered that it had underestimate[d] the depth of contamination during the original remedial design, [184] and consequently, it ordered additional sediment sampling (coring) to inform Phase 2 of dredging.[185] In addition to underestimating the depth and mass of PCB contamination, EPA also underestimated the concentration of PCBs in surface sediments.[186] Yet, despite acknowledging (1) that the 2002 ROD had underestimated the concentration, depth, and mass of PCB contamination in the sediment—*and* left more behind; (2) that operational adjustments meant dredging was not implemented in the manner anticipated in the 2002 ROD; and (3) the fact that dredging began later than anticipated in the ROD, [187] the Proposed Second FYR concludes that EPA s remedy for the sediments was implemented successfully and within expectations described in the ROD. [188]

1. Average Surface Sediment PCB Concentrations After Dredging Are Two to Three Times Higher Than Anticipated in the 2002 ROD, Undermining EPA s Will Be Protective Determination.

Surface sediment concentrations are the primary source of PCBs bioavailable to fish species, and are closely linked to fish tissue concentrations.[189] For this reason, reducing surface sediment concentrations of PCBs is essential to the RAO of reducing PCB concentrations in fish.[190] The 2002 ROD anticipated that the remedy (dredging followed by MNA) would reduce surface sediment Tri+ PCB concentrations from an average of 4.6 mg/kg for River Section 1; 2.26 mg/kg for River Section 2; and 0.53 mg/kg for River Section 3; to an average of 0.96 mg/kg in River Section 1; 0.08 mg/kg in River Section 2, and 0.51 mg/kg in River Section 3.[191]

In the First FYR, EPA used the surface sediment data collected during the Sediment Sampling and Analysis Program (SSAP) survey conducted from 2002-2005 as a pre-dredging baseline to re-estimate expected reductions in average Tri+ PCBs concentrations from implementing the dredging remedy.[192] The SSAP re-estimate with 2003 pre-dredging data found that, in actuality, two to three times *higher* Tri+ PCB concentrations existed in surface sediment.[193] Thus, as noted

[182] *Id.* at 60; *see also id.* at Table 10-1 (estimating total PCB mass removed to be 70,000 kg).

[193] 2012 FYR App x A at Table 1.

by NOAA, the higher than expected pre-dredging surface sediment PCB concentrations likely extend the time required to reach recovery thresholds in fish tissue.[194]

Utilizing incorrect inputs for pre-dredging surface sediment PCB concentrations also impacts EPA s model predictions for post-dredging concentrations. Similarly, the EPA s 2002 ROD prediction for post-dredging PCB surface sediment concentrations *underestimates* the PCB concentration in surface sediment after dredging.[195] After correcting this input assumption, NOAA found that post-dredging residual PCB surface sediment concentrations were three to five times higher than predicted in the 2002 ROD, with even greater differences for River Sections 2 and 3.[196] Even utilizing EPA s own projected 8% decay rate (which NOAA and others dispute), recovery would be delayed by 25 years.[197] Comparing the EPA s 2002 ROD predictions with observed post-dredging PCB concentrations in surface sediment, NOAA found this prediction borne out, as a three to five times higher PCB concentration was actually observed in surface sediment after dredging.[198]

EPA admitted in the First FYR that after re-estimating Tri+ PCB concentrations with SSAP data, higher concentrations of PCBs would remain in river surface sediment after dredging than anticipated by the 2002 ROD.[199] However, the agency does not take the logical next step in evaluating whether this will impact its current will be protective determination by undermining the assumptions held in the 2002 ROD. In the Proposed Second FYR Appendix 4, EPA describes average Tri+ PCB surface sediment concentrations remaining after dredging only in *percentages*.[200]

Rather than compare the actual observed reductions in PCB residual concentrations in surface sediment with the 2002 ROD expectations and targets, EPA compares this data with the less-stringent interim expectations described in the First FYR,[201] without any justification of why this is correct.

Table 3 shows EPA s comparison of the percentages of PCBs remaining by concentration in surface sediment after dredging between the First FYR re-estimate and the Proposed Second FYR observed data. Looking at the actual values of the residual PCB concentrations—rather than percentages—it becomes evident that the remedy as implemented does not conform with 2002 ROD expectations or meet remediation goals judged necessary to achieve protection of human health and the environment in River Sections 2 and 3. To elucidate this discrepancy, Table 3

[201] 2017 FYR App x 4 at 5-2.

compares the 2002 ROD expectations with the 2012 re-estimation and the 2017 actual observed surface sediment data.

TABLE 3

River Section (area weighted average)	**2002 ROD expectation**			**2012 FYR re-estimate (using 2003 pre-dredge data from SSAP survey)**			**2016 actual observed (from 2017 FYR)**	
	pre-dredge mg/kg [202]	post-dredge mg/kg [203]	% reduction	pre-dredge mg/kg [204]	post-dredge mg/kg [205]	% reduction [206]	post-dredge mg/kg [207]	% reduction [208]
River Section 1	4.6	0.96	79%	14.2	1.9	87%	0.77	96%
River Section 2	2.26	0.80	66%	11	7.1	36%	1.34	88%
River Section 3	0.53	0.51	4%	3.3	3.1	5.1%	0.83	80%

Looking at actual concentrations of residual PCBs in surface sediment, the remedy as implemented has *not* achieved the residual surface sediment PCB concentration goals in River Sections 2 and 3. This is because the pre-dredging PCB concentrations were much higher than anticipated. Because the 2002 ROD model predicting the rate of decay of residual PCB contamination has not been updated using the higher surface sediment concentration levels (the 2012 re-estimate), the model probably over predicts the rate of decay. EPA s will be protective determination is thus premised on inaccurate input assumptions, and cannot support the protectiveness determination.

2. <u>The Proposed Second FYR Misleadingly Compares Percentages of PCBs Removed with the 2002 ROD Percentage Reduction Goals in Concluding that the Goals Are Being Met, Despite Acknowledging that Up to Nearly Two and A Half Times More PCBs Were Found in Surface Sediment Than Expected.</u>

The Proposed Second FYR puts the remedy in the best possible light by stating that 72% of the overall PCB mass from the Upper Hudson River was removed by the dredging, which exceeds the 65% reduction assumed in the ROD. [209] This statement ignores the fact that more than two

[209] *Id.* at 32.

times more PCBs were found in the areas targeted for dredging than originally anticipated in the 2002 ROD.[210]

A less rosy picture is painted by examining the actual values of the total mass of PCBs removed by dredging—rather than percentages. Using this approach, it is evident that the remedy as implemented does not conform with 2002 ROD expectations, as shown in Table 4.[211]

TABLE 4	**ROD expectations (2002 ROD)**	**actual observed (2017 FYR)**
percentage of PCBs to be removed by dredging	65%	(72%)
mass of PCBs existing in dredging area	107,400 kg[212]	216,333 kg
mass of PCBs removed by dredging	69,800 kg[213]	155,760 kg[214]
residual PCBs after dredging	37,600 kg	60,573 kg

The 2002 ROD anticipated that 37,600 kg of total PCBs would remain after dredging had been completed. However, the Proposed Second FYR data indicates that 60,573 kg of total PCBs remained in the targeted river sections after dredging. This means that *much more PCBs remain* in the dredged areas than was assumed in the 2002 ROD.

Despite acknowledging that more PCBs remain than anticipated by the 2002 ROD—and, thus, that the remedy has not been implemented as described—EPA concluded that, after MNA, it will be protective of human health and the environment.[215] This conclusion ignores that the conditions the 2002 ROD predicted would exist after dredging, and upon which it prefaced its MNA determinations, were not achieved by the dredging, since at least two times more PCBs remain after dredging in the targeted river sections. With two times more PCBs remaining in the sediment in some areas, the 2002 ROD predictions about natural attenuation are significantly undermined, and cannot reasonably form the basis for EPA s will be protective determination.

The failure of the remedy to reduce the amount of residual PCBs after dredging to conform with the 2002 ROD expectations renders EPA s protectiveness finding arbitrary. EPA does not evaluate whether the fact that between two and nearly two and a half times more PCBs remain in the riverine environment will have an impact on the MNA process, potentially slowing natural recovery dramatically. The 2002 ROD itself rejected the alternatives employing MNA without

---

[210] *Cf.* 2017 FYR App x 8 at 2-4 (the PCB mass removed by dredging . . . was 2.3 times the prospective ROD estimate); *see also* 2017 FYR at 31 (underestimates of the depth of contamination [were]primarily caused by wood debris that interfered with sediment sampling); *id.* at 4 (Total PCB and Tri+ PCB mass removed were greater than planned, due to underestimates of the depth of contamination during the original remedial design. PCB mass in non-dredged areas is also greater than estimated in the 2002 ROD, although to a lesser extent than within the dredged areas.).

[211] *See also* NOAA Study at 495, Figure 5 (comparing, for each River Section, the extent to which more PCBs were present than anticipated prior to dredging and the higher-than-expected concentration post-dredging).

[212] *See* 2002 ROD at 21 (listing total PCB mass in the sediments in River Sections 1, 2 and 3).

[213] *See* 2017 FYR App x 2 at Table A2-3.

[214] *Id.*

[215] 2017 FYR at 24.

dredging in favor of a remedy that included dredging and subsequent MNA precisely because the slow remediation timeline presented was inadequate to protect human health and the environment.[216] Such slowing here, by leaving behind at least two times more PCB mass than anticipated, and three to five times more PCBs in surface sediments, similarly fails to protect human health and the environment.

DEC echoed this criticism of the Proposed Second FYR, explaining that the fact that sediment concentrations higher than anticipated will remain after dredging[] indicates that the targeted fish PCB concentrations will not be reached in the time frames identified in the ROD. [217] Both the greater-than-expected PCBs remaining after dredging and the operational delays in implementing the dredging contradict[] the basis upon which EPA selected the remedy, namely, that a delay in abating the uncontrolled ecological and human health exposures was not acceptable. [218]

Thus, not only does the Proposed Second FYR s comparison of the targeted river sections 2017 status with the 2002 ROD goals via percentages mislead the public with regard to the effectiveness of the dredging, but it also raises serious questions as to the accuracy of the EPA s finding that the remedy as implemented will be protective of human health and the environment.[219] Furthermore, DEC calls for the site conceptual model [] to be updated to take into account the data gathered [] since the ROD was issued that showed that higher surface sediment PCB concentrations would be left behind than anticipated . . . . [220] Similarly, NOAA calls for the model to be updated both with the increased PCB contamination input as well as the corrected rate of decay.[221]

Accordingly, EPA must require additional dredging to remove the remaining PCBs in accordance with the 2002 ROD expectations, or reevaluate the anticipated MNA rate to account for the two times more PCBs remaining in the environment, taking into account the inadequacy of slow MNA-only timelines rejected in the 2002 ROD.

C. Water Column

To reduce environmental and human health risks, the 2002 ROD proposed two remedial action objectives related to PCB concentrations in the Upper Hudson River water column: (1) to [r]educe PCB levels in sediments in order to reduce PCB concentrations in river (surface) water that are above surface water ARARs [applicable or relevant and appropriate requirements] ; and (2) to [m]inimize the long-term downstream transport of PCBs in the river. [222] PCBs that are transported downstream in the water column are available to biota, contributing to the risk to

---

[216] 2002 ROD at 73. *See also* DEC Report at 1 (EPA selected this remedy primarily based upon the time it would take to achieve targeted fish PCB concentrations after dredging. . . . Specifically, EPA stated in the ROD that a delay of ten years in dredging and 0.2 mg/kg within 16 years of the completion of dredging was unacceptable. This ten year delay was used as a basis for rejecting the Monitored Natural Attenuation (MNA) remedial alternative. . . . EPA conclude the dredging was needed to accelerate the time it would take to reach the remedial targets for fish flesh in order to quickly reduce human health and ecological risk compared other alternatives that were evaluated.).

[222] 2002 ROD at 51-52.

human health and the environment from the Site s PCB contamination. Downstream transport also moves PCBs from highly contaminated areas to lesser contaminated or clean areas, and from the Upper Hudson to the Lower Hudson.[223]

1. The 2002 ROD Predictions Were Optimistic for the Lower Hudson.

At the time the Proposed Second FYR was issued, EPA had compiled pre-dredging period water quality data for 17 years (1991-2008), dredging period data for six years (2009-2015), and post-dredging data for one year (2016). Despite having collected over 25 years of Hudson River PCB data, some of EPA s critical modeling failed to predict trends, concentrations, decay and volatilization rates of PCBs.[224] Furthermore, the model used to analyze Lower Hudson River data systematically under-predicted Tri+ PCB concentrations at Poughkeepsie.[225] Two of EPA s models disagreed on rates of decay and neither was accurate: decay was slower than the HUDTOX MNA model predicted at Stillwater and Waterford and faster than the 2002 ROD MNA model predicted at Thompson Island Dam and Schuylerville.[226]

EPA claimed that the 2002 ROD forecast rate of natural attenuation (9.6% - 10.6%) during the pre-dredging period (2004-2008) was comparable to the observed decay rates at the four Upper Hudson River stations (4.5% - 13.1%).[227] Although Tri+ PCB concentrations at the Albany station—the uppermost river segment of the two Lower Hudson stations—were in close agreement with the four Upper Hudson stations, the modeling used to predict Tri+ PCB concentrations at Poughkeepsie under-predicted concentrations for the pre-dredging period from 2004 to 2008.[228]

EPA has conceded that the effects of PCB load reduction from Upper Hudson to Lower Hudson are unknown. Additional years of monitoring data will be required to sufficiently evaluate MNA trends following completion of dredging activities. [229]

2. Load Reductions to the Lower Hudson Are Not as Large As Expected.

As HRF observes, in both the pre-dredging and post-dredging periods, Tri+ PCB concentrations decreased with increasing flow for river flows less than approximately 13,000 cfs (or 1.6 times the long-term mean river flow at Waterford) and [f]or river flows greater than 13,000 cfs, Tri+ PCB concentrations increased with increasing flows. [230] HRF indicates that the second result is expected, and is associated with increased flow-induced erosion of the streambed and the accompanying increase in suspended sediment loads (and particulate phase PCB transport) during the higher flows. [231] These findings also indicate that resuspension of

[223] *Id.*
[224] *See, e.g.*, 2017 FYR at 2-1 (The modeling analysis yielded much lower estimated concentrations of volatilized concentrations in the air compared to empirical data.).

[229] *Id.* at 2-6.
[230] HRF Report at ii, 7.
[231] *Id*. at 7.

localized sediments, rather than upstream inputs, is driving Tri+ PCB concentrations during high flow events.[232]

Modeling indicated a significant reduction in Tri+ PCB loadings during high flow events and minimal reduction during low flow events (*see* HRF Report Figure 9, reproduced below).[233] Even less reduction was predicted when based on the actual flow record from 2004 to 2008. Under this scenario, Tri+ PCB loads during the pre-dredging and post-dredging periods would be reduced by only 13% if pre- and post-dredging flows were comparable.[234]

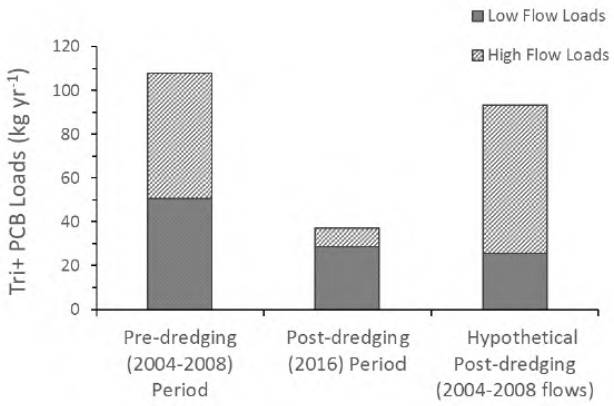

Figure 9. Estimated Tri+ PCB loads to the Lower Hudson for the 2004-2008 pre-dredging period, the 2016 post-dredging period and a hypothetical post-dredging period based on 2004-2008 flow record. Results are presented as stacked bars for low-flow (< 13,000 cfs) and high-flow (> 13,000 cfs) loads.

According to HRF,

> Tri+ PCB loads for low flow conditions were approximately 27 kg/yr for both the 2016 post-dredging period and hypothetical post-dredging scenario. This indicates that year-to-year variations in river flow will have a small effect on Tri+ PCB loads during low flows. However, Tri+ PCB loads during high flows showed large differences. This result indicates that Tri+ PCB loads during high flow conditions will likely show large year-to-year variations; e.g., from 8.3 kg/yr based on the 2016 flow record to potentially more than 100 kg/yr if the river experiences another year like 2011 with three major high flow events.[235]

[232] *Id.* at ii-iii.
[233] *Id.* at 34.
[234] *Id.* at 14.
[235] *Id.* at 14.

This analysis shows that EPA should never have expected dredging above the Federal Dam to have a major effect on the river downstream. This conclusion is further bolstered by existing post-dredging data, since 2016 was actually an abnormally low year in terms of PCB loading, but fish tissue levels still showed little to no recovery.

3. No Water Column Response Was Observed in the Lower Hudson and the Response Is Not as Anticipated in the Upper Hudson.

EPA s water column data to date shows that the impacts on water column PCB concentrations from dredging are much more immediate and localized than assumed in the 2002 ROD. Although Tri+ PCB concentrations in the Upper Hudson water column showed a relatively rapid response to the dredging, the Lower Hudson River has been slow to respond. This lag is due in part to the cyclic transfer between the surface sediment and water column during resuspension and deposition, and the fact that post-dredging Tri+ PCB concentrations averaged four times higher than predicted by the 2002 ROD models.[236] The result is that additional years of MNA will be required to reduce PCB concentrations in the water column—as well as in fish and sediment—to acceptable levels.

In short, dredging produced results in water column concentrations upriver, but not downriver. EPA s modeling is inadequate to predict if and when Lower Hudson water column PCB concentrations will reach the target concentration of 5 ng/L. Tri+ PCB concentrations at Lower Hudson River monitoring stations 1995-2016 show *no* decline,[237] and, contrary to the 2002 ROD expectations, the Poughkeepsie water column data showed no dredging impacts, suggesting that water column PCB concentrations are regulated by local conditions. [238] HRF attributed the faulty modeling at Poughkeepsie to the complexity of sediment transport and dynamic response in the Lower Hudson.[239] Ultimately, it is unlikely that activities or conditions in the Upper Hudson River will have any significant impact on water column concentrations below the Federal Dam, further supporting the need for a full remedial investigation and feasibility study of the Lower Hudson River.

VII. EPA Must Make a Not Protective Finding for the Lower Hudson.

In the Proposed Second FYR, EPA makes no protectiveness determination with regard to the Lower Hudson River—over 150 miles of the Superfund Site from the Federal Dam in Troy to the Battery in New York City. In contrast, in the First FYR, EPA found that the remedy will be protective for the entire 197-mile Superfund Site.[240] EPA is now walking back that conclusion, finding that the will be protective determination only applies to the Upper Hudson River—the 40 miles of the Superfund Site north of the Federal Dam.[241]

[236] NOAA Study at 499.
[237] 2017 FYR App x 1 at Fig. A1-2.
[238] *Id.* at 4-8.
[239] HRF Report at iii.
[240] 2012 FYR at vi, 40.
[241] 2017 FYR at 8, 24.

EPA s decision not to include a sitewide protectiveness determination is a major departure from the First FYR (although EPA fails to discuss it openly or clearly), and further evidences the need for a full remedial investigation and feasibility study for the Lower Hudson River. EPA s decision not to evaluate whether the remedy is protective for the lower 150 miles of the site renders the Proposed Second FYR deficient. The Lower Hudson River, which constitutes nearly 80% of the Hudson River Superfund Site, is lined with cities, towns, and villages that depend on the river for recreation, economic opportunities, and drinking water. Despite the significance of this portion of the Site, EPA has declined to make any protectiveness determination, essentially choosing to ignore the reality that the benefits of the sediment cleanup that were supposed to materialize downstream have not done so in any meaningful way.

If EPA had undertaken the required analysis for the Lower Hudson, it should have led the agency to conclude that a full remedial investigation and feasibility study for the Lower Hudson is necessary.[242] But, even without that analysis, EPA has enough information to reach the same conclusion. The Proposed Second FYR candidly states that data collected so far show that the active remediation—the dredging— in the Upper Hudson is not having any measurable impact on PCB contamination levels in the Lower Hudson.[243] In addition, the model that EPA relied upon to devise the 2002 ROD goals underestimated fish tissue concentrations in the Lower Hudson.[244] Furthermore, the Proposed Second FYR calls for more monitoring in the Lower Hudson,[245] although it fails to establish any mechanism or timeframe for this to take place.

In short, existing data shows that the remedy is not currently protective of human health and the environment in the Lower Hudson River. This is particularly troubling considering that many people in the Lower Hudson, including many New York City residents from low-income communities and communities of color, either rely on subsistence fishing from the Hudson River as an important source of food or would like to do so. The simple fact that subsistence fishing occurs in the 150-mile stretch of the Hudson River below the Federal Dam, particularly in and around New York City, reinforces the need for EPA to ensure that the cleanup is protective of the entire site. Omitting a protectiveness determination for this portion of the Site does nothing but create further concern and confusion among the millions of people who live, work, and play along the Lower Hudson from Troy to Manhattan.

VIII. Changes in Implementation of Dredging Project Do Not Explain Lack of Fish Recovery Within Expected Timeframes.

The selected remedy was premised on achieving a relatively rapid decline in fish tissue PCB concentrations, reaching a species-weighted average concentration of 0.4 mg/kg within five

[242] At the recent Informational Meeting in Poughkeepsie, NY, EPA officials stated that they weren t there yet when it comes to whether a RI/FS is warranted for the Lower Hudson River. *See* Oceans 8 Films, *Hudson River Action - Tell EPA: Protect people and wildlife, not GE* at minute 2:45 (June 28, 2017) *available at* https://vimeo.com/225670244. EPA itself in the 2017 FYR has called for more data collection in the Lower River, 2017 FYR at 57, but has not explained *how* such information collection will be conducted. Similarly, the 2017 FYR does not evaluate on what timeline such research will be undertaken, nor what event or evidence would trigger a full-blown RI/FS for the Lower Hudson River, rather than the mere additional information described in the 2017 FYR.

[243] 2017 FYR at 6, 33.

[244] NOAA Study at 499.

[245] 2017 FYR at 57.

years of the completion of dredging, or by 2020.[246] The most recent data from 2016 indicates that average fish tissue concentrations measured at 1.3 mg/kg,[247] or more than three times the 0.4 mg/kg target level. As discussed in more detail above, based on independent scientific analysis as well as analyses by DEC and NOAA, EPA s estimated 8% decay rate is not supported, and a significantly lower decay rate of 3-5% is likely more accurate.[248] However, even assuming *arguendo* that EPA s 8% rate is accurate, it is incredibly improbable that fish tissue levels will approach 0.4 mg/kg by 2020. In fact, at an 8% decay rate, it will take another 11 years to reach the five-year target; at a 5% decay rate, it will take another 18 years. In order to reduce 1.3 mg/kg to 0.4 mg/kg by 2020, the decay rate would have to be over 25%—a practical impossibility.

In an attempt to explain away this reality and justify its will be protective determination, EPA spent an entire appendix to the Proposed Second FYR discussing why fish tissue levels remain so far above the 2002 ROD expectations. EPA s unsubstantiated hypothesis is that changes in the implementation of the dredging project from what was anticipated in the 2002 ROD led to increased PCB levels in water that have delayed fish tissue recovery.[249]

The 2002 ROD anticipated that dredging would occur from upstream to downstream, and that two sediment processing facilities would be used, at least one of which would be located downstream of most dredging operations.[250] However, for various operational reasons, EPA determined that the project would follow a general upstream-to-downstream progression, but at times dredging would occur in multiple river sections at the same time, especially during the last two to three seasons of dredging.[251] EPA also decided to use a single, upstream facility, which resulted in more vessel traffic over the project area in the later years of dredging.[252] EPA claims that these operational changes resulted in increased levels of suspended PCBs over the entire project area and, therefore, fish tissue concentrations may still be within the ROD-anticipated period of equilibration. [253] Based on this rationale, EPA rejects attempts to compare observed data to ROD forecasts.[254]

However, EPA fails to mention that the 2002 ROD timeframes for the interim targets of 0.4 mg/kg and 0.2 mg/kg—within five years and 16 years after dredging, respectively—already took into account up to two years for equilibration. Thus, the time to reach equilibration should not be a justification to extend the interim targets even farther into the future.

A closer look at the Remedial Action Monitoring Program (RAMP) data also belies EPA s hypothesis. The expected fish tissue recovery trend can be described as a significant rapid decline in concentrations very soon after dredging (a step-function), followed by a reasonably

[246] 2002 ROD at 50; *see also id.* at 73 (Table indicating .4 mg/kg average fish tissue concentration will be reached in 2012, or three years after the then-expected end of dredging in 2009).

stable decay rate. This trend is illustrated by the fish recovery trends for the Cumberland Bay-Wilcox site, highlighted by EPA in Figures A8-5.1 and 5.2 in the Proposed Second FYR. Upon a review of the project data, it is apparent that the step-function decline seen at Cumberland Bay in two to four years post-dredging have already occurred for the vast majority of species at the vast majority of stations along the Hudson River Site. This indicates that fish tissue levels have likely already reached equilibrium. Fish tissue levels elevated beyond what was expected at this point post-dredging are probably *not* short-term impacts due to differences in project implementation, but an indication of a significant delay in long-term recovery with negative implications for the protectiveness of the remedy.

This step-function trend is visible in Figures 5A-5R of the SSPA Report and in Figures A8-4.1-4.12 of the Proposed Second FYR. For nearly every species at every station, one discerns a trend where in the pre-dredging period concentrations remain more or less stable, and then when dredging occurs near a particular station, one observes an increase in concentrations for one or two data points. Following the increase, there is a clear, sharp decline for the one to two years. That sharp decline subsequently stabilizes into a slow, gradual decline.

EPA itself admits that [i]n general, fish tissue PCB levels were observed to recover to pre-dredging levels within one to three years after completion of dredging upstream of a monitoring station. [255] In River Section 1, the RAMP data indicates that fish tissue levels peaked within one to two years after dredging, then rapidly declined.[256] For River Section 2 and River Section 3 the same general patterns prevail, with very few exceptions (e.g., black bass at fish monitoring stations SW1 and ND2).[257] Out of 20 measured trends in River Section 1 (four species each at five stations), 16 trends have already declined to at or below the Baseline Monitoring Program (BMP) mean, and 15 have decreased below the Lower Confidence Level (LCL) of the BMP as of 2016 – indicating they have reached or surpassed equilibrated levels.[258] Out of 16 trends in River Section 2 (four species each at four stations), 13 have declined to or below the BMP mean and 11 have declined to or below the BMP LCL.[259] In River Section 3, all 20 trends (four fish each at five stations) were at or below the BMP mean in 2016, although only 11 have fallen below the BMP LCL.[260] EPA also stated in a presentation to the Community Advisory Group for the Site that fish tissue concentrations decrease rapidly following spikes related to environmental dredging at other sites, and that the agency likewise expects a rapid return to baseline in the Hudson River.[261]

In short, post-dredging equilibration has already occurred in the Upper Hudson River. There has already been a large step-down in fish tissue concentrations as a result of the dredging, and from this point forward, EPA should only anticipate a stable decay rate in the absence of further removal or sequestration of PCBs. Moreover, Figures A8-1 and A8-2 demonstrate the extent to

[261] U.S. Envtl. Prot. Agency, *Powerpoint: PCBs in Fish Tissues at the Hudson River PCBs Superfund Site: Update on Results of Baseline and Remedial Action Monitoring (2004-2013)* at 18 (Oct. 30, 2014) *available at* http://www.hudsoncag.ene.com/files/FishDataSummaryOct2014.pdf. (Attachment R)

which the 2002 ROD envisioned dredging approach was consistent with actual implementation. As EPA states, there are some deviations from the way in which the 2002 ROD contemplated the dredging project. However, the 2002 ROD approach and actual project approach are remarkably similar, with few relatively minor deviations (i.e., dredging an upstream Certification Unit (CU) one dredging season prior to the CU immediately downstream). A notable exception is the dredging upstream of the TD1 monitoring station in River Section 1 in 2015, but this is an outlier to the general pattern. Overall, it is apparent that the dredging program progressed more or less as planned. EPA simply does not have adequate justification to identify these changes in implementation as the main reason fish tissue levels remain elevated.

In sum, the data does not support the idea that fish tissue concentrations are still being significantly impacted by the dredging activity. The expected step-function drop in fish tissue levels has already occurred; in most species at most stations, the fish have already equilibrated. Thus, EPA is left with fish tissue concentrations that are more elevated than expected at the time of the 2002 ROD and it is very unlikely that these concentrations will decline at the rate EPA predicted. In light of these conditions, the agency needs to take a hard look at what went wrong and what must be done to ensure the RAOs are met within the approximate timeframes set forth in the 2002 ROD.

IX. EPA Failed to Act On the Follow-Up Recommendations and Key Concerns from The 2010 Peer Review Panel, the Natural Resource Trustees, New York State, and the Hudson River Foundation To Adaptively Manage the Remedy.

Since at least 2010, scientists from federal, state, and independent institutions have repeatedly shared with the EPA and the public substantive and credible analyses that clearly indicate the Hudson River Superfund Site remedy and cleanup to date is *not* protective of human health and the environment.

A. 2010 Peer Review Panel Findings.

In the Spring of 2010, a panel of seven independent scientists selected by both the EPA and GE was tasked with evaluating all aspects of Phase 1 dredging operations from the first year of active remediation and reporting back recommendations for changes to remedial designs for Phase 2 operations. The panel s report was released in September 2010.[262] While the Panel acknowledged there were serious challenges in Phase 1, it recommended that with appropriate adjustments based on good data and sound science, Phase 2 remedial action should proceed. One of the most critical observations (and resulting recommendation) made by the panel was that neither EPA nor GE has sufficient data or a credible tool to project recovery.[263] The panel stated that the HUDTOX/FISHRAND models (originally used during development of the 2002 ROD) are outdated and inadequate to accurately project MNR and post- dredge fish recovery rates.[264]

---

[262] *See generally Hudson River PCBs Site Peer Review of Phase 1 Dredging* (Sept. 10, 2010) [hereinafter Phase 1 Review] *available at* https://www3.epa.gov/hudson/pdf/hudsonriverphase1dredgingreport_final.pdf. (Attachment S)

[263] *Id.* at 13.

[264] *Id*.

The panel told EPA and GE that in order to create more effective and comprehensive dredge-design paradigms for successive remediation protocols, they should collaborate on the creation of a new Fate, Transport and Risk Model utilizing the real-time data collected during the first phase of dredging and data from year one of Phase 2. The updated fate, transport, and risk model would enable EPA and GE to better understand the implications of operational changes on long-term recovery rates, and would support EPA and GE in making appropriate and meaningful risk management decisions about dredging productivity, BMPs, and the long-term fate and transport of PCB residuals and resuspension and release.[265]

The panel further advised the five-year timeline for project duration should be extended to provide necessary flexibility to meet the actual remediation need of the river while protecting long-range remedy goals. Finally, the panel stated that there should not be a limit on the PCB mass to be removed during remediation as the total amount of PCB inventory in the river is unknown.

B. Federal Trustees Study Supports A "Not Protective" Determination.

In direct contradiction to the conclusions made by EPA Region 2 staff in the First FYR and in the Proposed Second FYR, scientists from federal, state and independent institutions have shared with EPA and with the public substantive and credible analysis that clearly indicate the Hudson remedy and the cleanup action to date is not protective of human health and the environment as implemented.

In an inter-agency communication to EPA Region 2 and in a peer-reviewed study,[266] NOAA informed EPA that recovery of the Upper and Lower Hudson will not be reached due to elevated PCBs remaining in surface sediment equivalent to a series of Superfund Sites being left behind, [267] and that post-remedial PCB concentrations in the Upper Hudson River sediments will exceed previous EPA model predictions by a factor of 3-to-5 times. [268] The Trustees also warned EPA that achieving the Remediation Goals for PCB fish tissue concentrations in the Lower Hudson River would take several decades longer than expected,[269] and that additional removal of PCB-contaminated sediment in the [Upper Hudson] [is] needed to achieve reductions in [Lower Hudson] fish PCBs anticipated in the ROD. [270]

C. New York State Analysis and Review Support A "Not Protective" Determination.

Acting on behalf of the interests of New York State and its citizens, the Office of the Attorney General (OAG) notified EPA in September 2016 that it is now clear that the remedy has not met the remedial action objective of reducing PCB concentrations in fish to 0.4 mg/kg by 2016, and may not reach the ROD s more dramatic reductions to 0.05 mg/kg. [271]

The OAG advised the EPA that it must determine with reasonable certainty the time-frame by which there will be a reduction of PCB concentrations in fish so that fish consumption advisories for PCBs may be lifted in all contaminated River reaches of the Hudson River for all species and that EPA s determination of remedy s protectiveness must be supported by a comprehensive Fish Consumption Survey to quantify current and potential future human exposure. [272] Furthermore, the OAG insisted that EPA must clearly define the time-frame for achieving the remedial action objectives set forth in the ROD and cautioned that in evaluating that time-frame, EPA must take into account the change in fish tissue sampling that occurred during GE s implementation of the baseline and remedial fish monitoring.[273] The OAG letter reflects the State s deep concerns regarding localized effects of human exposure in certain more contaminated areas of the River and urged EPA to evaluate those effects as part of EPA s Five Year Review and protectiveness determination. [274]

In December 2016, the DEC—a Hudson River Superfund Site Trustee and primary natural resource manager for the State s natural resources— issued a preliminary review of the effectiveness of the cleanup to date.[275] DEC concluded that the Remedy is not protective of human health and the environment based on uncontrolled risks, and EPA should undertake all necessary actions to ensure that the remedy becomes fully protective to the benefit of the people of New York State. [276]

DEC s review identified a serious failure that EPA continues to dismiss: that there are known exposures to both human and ecological receptors which have not been controlled and which remain in excess of EPA s acceptable risk range. [277] Moreover, sediment concentrations higher than anticipated will remain after dredging, [which] indicates that the 3 targeted fish PCB concentrations will not be reached in the time frames identified in the ROD. [278] DEC recommended that EPA optimize the remedy through further remedial work as necessary to achieve the targeted fish PCB reductions identified in the ROD. [279]

DEC s review also underscores the failure of the remedial action to achieve benefits in the Lower Hudson River. As such, DEC informed EPA that it must expand the investigation of the site to include performance of a Remedial Investigation and Feasibility Study for the portion of the site between the Federal Dam at Troy and the Battery in New York City . . . to address the currently uncontrolled unacceptable risks to human health and the environment.[280]

D. Hudson River Foundation Report Does Not Support "Will Be Protective" Determination.

In fall of 2016, HRF directed a team of independent scientists and engineers with a wealth of expertise related to PCBs and the Hudson River to review project data related to the Upper Hudson Superfund dredging program. [281] On June 1, 2017, HRF released its report, finding that based on 2016 post-dredging monitoring, TPCB concentrations in fish throughout the Upper and Lower Hudson remain above interim target levels and remediation goal specified in the ROD. [282]

Similar to concerns expressed by NOAA and DEC, HRF observed that EPA has not planned an adequate data collection program to find out if monitored natural attenuation will work as expected. HRF advised that modifications to the post-dredging monitoring program and continued evaluation of the next few years of monitoring data are therefore recommended to assess if natural attenuation will be sufficient in reducing PCB concentrations in fish in a reasonable time frame or if additional remedial actions will be required. [283]

The panel corroborated the findings of DEC and the Federal Trustees that a major assumption in the ROD—that the Lower Hudson would receive similar benefits from the dredging action in the Upper Hudson—did not, and is not, likely to occur. In fact, water column, sediment and fish in the Lower Hudson below Albany are showing slow responses to the Upper Hudson dredging program. [284] This may be due to the complexities of sediment transport in the Lower Hudson [285] as noted by HRF, but the indisputable fact is the lower portion of the Superfund Site is showing little or no benefit from the dredging in the Upper Hudson. Over the past 10 years, 5.2 million pounds of PCB-contaminated sediment have landed in the Lower Hudson, presenting an uncontrolled risk that EPA is failing to address.

While HRF did not seek to answer the question of whether the cleanup of the Hudson River Superfund Site is protective, it did analyze all available project data, concluding that there is not enough post-dredging information to make a definitive conclusion regarding the success of the remedy.[286] HRF suggests that a fuller and more comprehensive analysis of the effects of the

dredging will be possible as new data are collected and other evaluation tools, such as numerical models, are utilized in understanding the longer-term impacts and trajectories. [287]

X. Answering the Three Five Year Review Questions Result in the Conclusion That Remedy is Not Protective of Human Health and the Environment.

Question A: Is the remedy functioning as intended? NO.

As discussed in detail in herein, current data demonstrates that the remedy is not functioning as intended. While removal of PCB-laden sediment has resulted in some reduction in fish tissue, surface sediment, and water PCB concentrations, the fact remains that all three media were far more contaminated than EPA believed at the time it issued the ROD. EPA failed to reevaluate its chosen remedy in light of this information, despite disagreement from its sister federal agencies, New York State, and independent scientists, as well as environmental organizations and the public.

As a result, fish tissue levels remain 300% greater than the first interim goal—0.4 mg/kg—which, according to the ROD, should be reached in less than three years, by 2020. Even EPA acknowledges that it is extremely unlikely this target will be met. In addition, EPA admits that the Lower Hudson is not responding as predicted to the dredging upriver and that it appears that local sediments, rather than upstream load, are the main driver of fish body burdens of PCBs.

Question B: Are the exposure assumptions, toxicity data, and Remedial Action Objectives used at the time of the remedy still valid? NO.

EPA has failed to acknowledge in the Proposed Second FYR any new information related to exposure assumptions or toxicity data that could impact the human health risk assessment. First, recent science indicates that PCBs are more toxic than previously thought. While EPA is still classifying PCBs as probable human carcinogens (EPA has not officially changed the Integrated Risk Information System listing, toxicity values or carcinogenicity of PCBs in the last 17 years[288]) with a cancer weight-of-evidence classification B2,[289] the International Agency for Research on Cancer (IARC), of the World Health Organization, has now listed PCBs as a known human carcinogen.[290] In addition, dioxin-like PCBs can now be evaluated via EPA s listing of non-cancer endpoints for dioxin[291] via the reference dose (RfD)[292] in EPA s

[292] An estimate (with uncertainty spanning perhaps an order of magnitude) of a daily oral exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects

Integrated Risk Information System (IRIS)[293] as well as several additional toxicological endpoints which have been updated in terms of health effects.

Second, recent science indicates that exposure to PCBs through inhalation is a more significant risk than previously believed. The risk characterization of the ROD and the intention of the RAOs are primarily intended to control unacceptable PCB exposures through consumption of contaminated food (i.e. fish). [294] However, since 2002, the scientific community has documented that exposures to PCBs can occur through contaminated water, direct skin contact, or breathing contaminated air.[295] In a 2015 Review of Scientific Literature, David O. Carpenter, M.D., presents information that indicates the inhalation of vapor-phase PCBs may be as or even more important than ingestion via fish consumption and other animal fats.[296] The research highlights the severity of the potential risks from volatilized or airborne PCBs, which have been associated with certain chronic illnesses—such as cancer, cardiovascular disease, hypertension, and diabetes—even at relatively low levels.[297]

All of this information adds to the growing body of research which demonstrates that PCBs are more toxic to humans than previously believed when the human health risk assessment was being developed for the ROD. As a result, the Proposed Second FYR needs to address the greater toxicity as a change in assumptions and new information that was not available at the time the ROD was developed.

Finally, significant changes in demographics and fish consumption patterns on the Hudson River, particularly in the Lower Hudson, mean that more people are relying on Hudson River fish for subsistence than at the time the ROD was issued. Due to the failures of longstanding fish consumption advisories to protect human health, an uncontrolled exposure through consumption of fish. Recent angler surveys have shown consumption of fish from the Hudson River remains a major health concern despite the existence of longstanding NYSDOH fish consumption advisories. In 2012, the Cornell Cooperative Extension performed a survey of over 300 anglers, finding that approximately 11% of those surveyed ate Hudson River fish.[298] In 2013, NYSDOH

presented preliminary results of its own angler survey showing even higher consumption percentages (near 50%), also noting that awareness of fish consumption advisories in the more populated and linguistically diverse Lower Hudson was about half of what it was in the Mid- and Upper Hudson regions.[299]

Since 2000, additional populations that rely on subsistence fishing have moved into Mid- and Lower Hudson River communities, and surveys indicate these anglers feed fish to their families.[300] The Proposed Second FYR also fails to consider these changes in subsistence fish consumption patterns, which increase exposure and human health risks. Subpopulations of subsistence anglers are currently consuming small forage fish in ways that not been included in the human health risk assessment, such as utilizing the entire fish in preparing spiced whole fish mash or paste for flavoring traditional dishes. Previous risk assessments were limited to the risks of consuming larger, traditional trophy or game fish, such as bass and perch. It is important that the exposure assumptions take into account all of the consumption patterns order to accurately capture the risks that the Hudson River Superfund Site poses to human health.

Question C: Has any other information come to light that could call into question the protectiveness of the remedy? YES.

The decision-making process that led to the ROD relied on a complex suite of human health risk assessment tools and guidelines, [301] as well as multiple sediment and water sampling programs. Those were in turn used by EPA and GE as the baseline informational database used in multipart mechanistic mathematical models to forecast future concentrations of PCBs in the Hudson River.[302] While the extensive body of scientific information for the site was appropriately employed in the remedy selection, EPA has failed to apply that same diligence to the evaluation of the newest scientific analysis and actual project data in the Proposed Second FYR.

Post-ROD data collected after 2002 show higher levels of surface sediment contamination than anticipated in portions of River Sections 2 and 3 that were not targeted for dredging. In fact, analyses of post-ROD data indicate that post-remediation PCB concentrations will be five times higher than assumed by the ROD. These residuals raise significant scientific uncertainty as to whether all RAOs, including target PCB levels in fish, will be fully achieved.

Furthermore, sediment and bioaccumulation models (HUDTOX and FISHRAND) used in the ROD are no longer considered scientifically valid. The models require re-examination, in light of

[302] *See* DEC Report.

the above-referenced data, to determine the likelihood that RAOs will be fully achieved. Post-Phase 1 modeling by GE validated the ROD s conclusions that dredging of contaminated sediment does not impede recovery of the river through resuspension of PCBs, but rather achieves significant progress towards RAOs by removing PCBs from the system.[303] However, neither this model nor any other updated sediment transport or bioaccumulation model has been used to date to evaluate how much higher-than-expected surface sediment PCB concentrations outside of the area targeted for dredging will impact the ability of the remedy to be protective of human health and the environment in the future.

XI. EPA Must Take the Following Actions Necessary to Ensure Protectiveness.

A. Clearly Define Goalposts for Success and Failure of the Cleanup and Order Additional Remediation.

EPA s Proposed Second Five Year Review of the Hudson River Superfund Site lacks clear metrics to evaluate the success or failure of the cleanup. Without clear metrics, the public is left in the dark as to how EPA compared current conditions with the 2002 ROD expectations to reach its conclusion that the remedy will be protective. Therefore, we urge EPA to identify and list the criteria that it used to evaluate the performance of the remedy in the Final Second FYR, as well as the criteria that the agency will use for subsequent reviews. This should lead to a fair consideration of all relevant targets, not a selective view of only the targets that are being met.

The interim and final fish tissue concentration targets should be among the most important benchmarks that EPA uses to evaluate the success or failure of the remedy. Despite EPA s reliance on the accelerated timelines to meet fish tissue targets in selecting the remedy, the agency fails to measure current conditions against them in a straightforward way. This is not acceptable. Clear benchmarks, measured in years after dredging, would ensure that all interested stakeholders—GE, Federal Trustees, DEC, community and environmental advocates, and the public—understand whether the cleanup is making the necessary progress toward protection of human health and the environment. Moreover, benchmarks would ensure that EPA, and in turn, GE, can be held accountable for cleaning up the River *within in the timeframes anticipated in the 2002 ROD*.

We urge EPA to expressly include at least the following benchmarks as a way to measure the success or failure of the remedy to protect human health and the environment both in subsequent five-year reviews and as more data becomes available each year:

1. Species-weighted fish fillet Upper Hudson average PCB concentrations must be at or below 0.4 mg/kg within five years of the completion of dredging (by 2020).
2. Species-weighted fish fillet Upper Hudson average PCB concentrations must be at or below 0.2 mg/kg within sixteen years of the completion of dredging (by 2031).
3. Largemouth bass, whole body PCB concentrations must be within the recalculated range of 0.2 mg/kg to 0.07 mg/kg within 23 years of the completion of dredging (by 2038).
4. Species-weighted fish fillet River Section 3 average PCB concentrations must be at or below 0.05 mg/kg within 43 years of the completion of dredging (by 2058).

[303] *See* Phase 1 Report.

Because the selected remedy is not currently protective, and people are still face unacceptable human health risks *daily* due to PCB contamination, EPA should further clarify that failure to meet these benchmarks means that the remedy is not functioning as intended. EPA should also develop a plan for adaptive management so that it is prepared to address potential problems with the remedy as they become apparent.

Moreover, the failure to meet the benchmarks should indicate to the agency that further active remediation is necessary. As discussed *supra*, the time to reach the human health targets was an important factor in EPA s selection of an active remedy. EPA s own rationale makes it clear that delays of ten or more years in reaching the interim and final 2002 ROD targets are unacceptable. Therefore, failure to meet the benchmarks within the timeframes anticipated in the ROD— including the current failure to meet the five-year target— should prompt EPA to order GE to perform additional remedial action. Finally, EPA should consider adding species-specific or more geographically limited targets, as well as ecological targets, to the criteria that evaluates to determine the success or failure of the remedy.

B. Immediately Order GE to Initiate a Remedial Investigation and Feasibility Study for the Lower Hudson.

EPA implicitly admits that the cleanup is not protective of human health and the environment in the Lower Hudson River by omitting a protectiveness determination for the 150-mile stretch below the Federal Dam.[304] As discussed above, in the First FYR, EPA issued a sitewide protectiveness determination for the entire 197-mile Superfund site.[305] However, the Proposed Second FYR contains no such determination.[306] While EPA claims that the cleanup will be protective in the Upper Hudson River (despite evidence to the contrary discussed herein), EPA makes no official protectiveness determination about the cleanup for the 150-mile stretch of the Hudson River below the Federal Dam.[307]

It is abundantly clear that EPA should order a full remedial investigation and feasibility study for the Lower Hudson River. EPA admits that fish tissue concentrations in the Lower Hudson River are not responding as anticipated; EPA concedes that the Lower Hudson is responding more slowly under MNA; and EPA recognizes that there is little to no change in fish tissue concentrations from Poughkeepsie downstream. Furthermore, the remedy only produced results in water column concentrations upriver, not downriver, indicating that it is unlikely that additional activities in the Upper Hudson River will have any significant impact on the Lower Hudson River.

While EPA says it will continue to investigate the Lower Hudson, it provides no specific plan of action to do so and no criteria to indicate under what conditions it would order a remedial investigation and feasibility study. That is not acceptable. Evidence right now suggests that there is a disconnect between the remedial activities in the Upper Hudson River and the response in

[304] *Id.* at 8.
[305] 2012 FYR at iv, 40.
[306] *Compare* 2017 FYR at 8, 24, 70 *with* 2012 FYR at iv, 40.
[307] *See* 2017 FYR at 8, 24, 70.

the Lower Hudson River. As such, EPA should immediately require GE to conduct a full remedial investigation and feasibility study to address the ongoing PCB contamination in the Lower Hudson River.

C. Collect Additional Data as Expeditiously as Possible.

Among the few points of consensus in EPA s Proposed Second Five Year Review is the need for more data to predict future trends. EPA must ensure that future data collection takes into account expert advice, including that of DEC and HRF.

DEC maintains that a more robust fish and sediment sampling program is necessary for the Hudson River Superfund Site.[308] An expanded sampling program would allow EPA to determine if the current surface sediment PCB concentrations are capable of meeting the intent of the ROD. [309] DEC also recommends that EPA utilize a pool by pool scale in designing the sampling program to better understand the progress made as a result of the remedy.[310]

While EPA claims that it needs eight to ten more years of data, HRF s report suggests that a more reliable sampling program would allow EPA to begin to evaluate future trends much sooner—as early as a couple of years from now. Specifically, HRF recommends that:

(i) EPA Method 1668 (a high resolution, congener-based method) should be used to improve the accuracy and reproducibility of PCB water column, sediment, and fish measurements,
(ii) the USGS suspended sediment monitoring at Waterford should be re-instated to support evaluations of PCB loads to the Lower Hudson,
(iii) additional high flow samples should be collected at Waterford to support evaluations of PCB loads to the Lower Hudson for high flow conditions, and
(iv) PCB concentrations should be monitored in surface sediments and sediment cores from selected locations in the Lower Hudson to improve our understanding of time responses in the tidal freshwater and estuarine portion of the river. [311]

EPA cannot take a wait-and-see approach to data collection, kicking the can down the road to the *next* five-year review or the one after that. While EPA is collecting data, people and wildlife continue to be exposed to dangerous levels of PCBs on a daily basis. EPA must devise fish, sediment and water sampling plans that gather data in an aggressive manner to discern the effectiveness of the remedy as quickly as possible.

[308] DEC Report at 2 (recommending that EPA perform the sampling work necessary to complete a detailed evaluation of the performance of the remedy, including increasing the sampling of sediment and fish tissue to the scale and frequency necessary to optimize the remedy through further remedial work as necessary to achieve the targeted fish PCB reductions identified in the ROD).
[309] *Id.* at 28 (also stating that the current EPA approved sampling plan is not designed to answer that question with the appropriate degree of statistical certainty.).
[310] DEC Report at 40.
[311] HRF Report at iii; *see also id.* at 19-20.

D. Update the HUDTOX and FISHRAND Models.

Using model emulation, NOAA has found that the higher than anticipated residual PCBs could lead to lengthy delays in fish recovery times.[312] In addition, as discussed *supra*, projections of fish recovery indicate considerable delay in the short-term targets. Moreover, estimates of the amounts of PCBs in the sediment changed dramatically after the ROD was issued. Under these circumstances, it is unreasonable to continue to rely upon simulations from a model that is now wholly outdated. Instead, EPA should develop a new transient model that takes account of all the observed data collected during the dredging phase and can provide useful short-term simulations of fish recovery.

E. Evaluate Effectiveness of NYSDOH Fish Consumption Advisories.

EPA did not evaluate the effectiveness of the institutional controls, such as NYSDOH s fish consumption advisories, in addressing the human health risks associated with PCB contamination. Understanding that institutional controls are an imperfect means of managing risk, the 2002 ROD only included them because of the limited time period for which the most restrictive fish consumption advisories would remain in place (i.e., until the interim goals were met). Currently, however, the remedy is failing to meet the ROD goals in the Upper Hudson River, and the remedy is having little to no impact on the Lower Hudson River. The known ineffectiveness of the institutional controls, particularly in light of the remedy s failure to meet the interim goals, means an impermissible level of risk to human health currently exists at the Hudson River Superfund Site.

Furthermore, EPA has not conducted sufficient outreach to subsistence anglers regarding the risks of consuming Hudson River fish. EPA s repeated reliance (particularly in the agency s recent Public Information Meetings) on NYSDOH s fish consumption advisories is insufficient. Despite acknowledging that the fish consumption advisories are *not* successful in preventing people from consuming PCB contaminated fish in unsafe amounts, EPA continues to insist that the implementation of NYSDOH s institutional controls are not within its jurisdiction. However, EPA holds the ultimate statutory responsibility for reducing risk to human health and the environment. If the NYSDOH fish advisories are inadequate to protect the public from PCB contamination risks (as DEC contends, in contrast to EPA s statements in the Proposed Second FYR[313]), *EPA* must either find ways to make those controls protective or implement additional controls. Therefore, it is imperative that EPA improves outreach to communities that are most likely to engage in subsistence fishing.

F. Update the Community Involvement Plan for the Hudson River Superfund Site.

EPA is not performing adequate outreach to communities along the length of the Site. While EPA has a Community Involvement Plan (CIP), it has not been updated in approximately eight

[312] NOAA Study at 495.

[313] *Compare* 2017 FYR at 24 (In the interim, human exposure pathways that could result in unacceptable risks are being controlled.) *with* DEC Report at 27 (Available information indicates that people continue to eat fish despite the institutional controls, and that these exposures represent human health risk beyond the EPA acceptable risk range.).

years.[314] The most recent update to the CIP, in 2009, was only intended to guide activities through the completion of dredging. [315] Now that dredging is complete, EPA should revise the CIP to better address the ongoing risks associated with PCB contamination that will continue for decades along the entire Hudson River Superfund Site.[316]

Although the Proposed Second FYR discusses additional measures mentioned in the First FYR,[317] the agency failed to organize any outreach to environmental justice communities during this comment period. In updating the CIP, EPA should ensure that its outreach extends to the diverse communities present along the Lower Hudson River. The CIP indicates that EPA s community involvement efforts have largely focused on upriver communities.[318] However, communities along the Lower Hudson River, including low-income communities, communities of color, and subsistence fishing communities, will also be exposed to PCB contamination for the foreseeable future.

EPA s community involvement goals include providing understandable information to the public, ensuring that the public has a meaningful opportunity to engage with EPA, and helping the public understanding the Superfund decision-making process.[319] However, it is difficult to understand how many of EPA s community involvement activities could actually meet these goals as they relate to downriver communities. For example, it is not reasonable to expect people who live near the Lower Hudson to benefit from EPA s enhanced physical presence in the Upper Hudson through field offices, public meetings, community events, and media appearances. Additionally, EPA recognizes that the far more populated and diverse Lower Hudson is home to a greater number of non-English speaking residents.[320] However, there is no indication that EPA has made specific efforts to ensure that its outreach materials, like fact sheets, technical documents, and e-mails, are widely available to various audiences.

The CIP s goal with regard to environmental justice is to increase awareness and information about the project, especially in communities that may not know how to access information or that may not have many opportunities or methods to do so. [321] We urge EPA to take a hard look at whether the agency is meeting this goal. EPA originally only scheduled two public information meetings on the Proposed Second FYR, neither of which were located in or near New York City. Moreover, it was clear from the first public information meeting in Poughkeepsie that EPA has failed to undertake sufficient outreach to subsistence fishing communities. When asked who among the crowd of over 300 people was a subsistence fisher, not a single person raised their

hand. EPA should follow its own directive from the CIP, and seek assistance from agencies who work with immigrant, low-income, and non-English speaking communities to inform people about the extent of the contamination in the river and the existing fish consumption advisories.[322] EPA should also consider developing specific strategies for reaching out to underrepresented communities, as it has done in other locations.

XII. Conclusion

For the aforementioned reasons, EPA must find that the remedy for the Hudson River Superfund Site is not protective of human health and the environment in its Final Second FYR. EPA s preliminary determination that the Hudson River remedy will be protective of human health and the environment is arbitrary and capricious and not supported by data and analyses by independent scientists, the Natural Resource Trustees for the Site, and New York State. The Final Second FYR must outline next steps toward additional remediation of the Upper Hudson to meet the remedial objectives within the timeframes set forth in the 2002 ROD. Moreover, the Final Second FYR must include a commitment to a full remedial investigation and feasibility study of the Lower Hudson River. A finding by EPA that the remedy is not protective will put the entire Hudson River on the path to quicker recovery, and will realize the Superfund program s goal of protecting the health of the people and wildlife living in and around the Hudson River.

Preface

The U.S. Environmental Protection Agency (EPA) is issuing this "Comprehensive Five-Year Review Guidance" to assist EPA Headquarters (HQ), Regional staff, and support agencies responsible for conducting five-year reviews under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). This guidance generally is intended to promote consistent implementation of the five-year review process.

Section 121 of CERCLA, as amended by the Superfund Amendments and Reauthorization Act of 1986 (SARA), requires that remedial actions which result in any hazardous substances, pollutants, or contaminants remaining at the site be subject to a five-year review. The National Oil and Hazardous Substances Pollution Contingency Plan (NCP) further provides that remedial actions which result in any hazardous substances, pollutants, or contaminants remaining at the site above levels that allow for unlimited use and unrestricted exposure be reviewed every five years to ensure protection of human health and the environment.

The Five-Year Review requirement applies to all remedial actions selected under CERCLA §121. Therefore, sites with CERCLA remedial actions may be subject to a five-year review. Consistent with Executive Order (EO) 12580, other Federal agencies are responsible for ensuring that five-year reviews are conducted at sites where five-year reviews are required or appropriate.

This guidance is designed and intended to:

- Provide an approach for conducting five-year reviews;
- Facilitate consistency across the ten EPA Regions;
- Clarify current policy; and
- Discuss roles and responsibilities of various entities in conducting or supporting five-year reviews.

This guidance supersedes the following directives on five-year reviews:

- Office of Solid Waste and Emergency Response (OSWER) Directive 9355.7-02 (May 23, 1991), *Structure and Components of Five-Year Reviews*;
- OSWER Directive 9355.7-02FS1 (August 1991), Factsheet: *Structure and Components of Five-Year Reviews;*

- OSWER Directive 9355.7-02A (July 26, 1994), *Supplemental Five-Year Review Guidance;* and

- OSWER Directive 9355.7-03A (December 21, 1995), *Second Supplemental Five-Year Review Guidance.*

In addition, this guidance updates and supersedes the text regarding five-year reviews in:

- OSWER 9200.1-23P (July 1999), *A Guide to Preparing Superfund Proposed Plans, Records of Decision, and Other Remedy Selection Decision Documents.*

Questions or comments concerning this guidance should be directed to the appropriate EPA Headquarters Regional Center.

1.0 OVERVIEW

This chapter covers the purpose of five-year reviews, when are reviews required or appropriate, discontinuation of five-year reviews, and triggering actions for five-year reviews. This chapter also discusses the application of the Five-Year Review policy to sites with multiple operable units (OUs), division of large complex sites, pre- and post-Superfund Amendments and Reauthorization Act of 1986 (SARA) sites, Records of Decision (RODs), and deleted or partially deleted sites. You will also find information on Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) remedial actions (RAs), CERCLA remedial actions at sites with Resource Conservation and Recovery Act (RCRA) response, and interim/early remedial actions. Finally, the chapter discusses how no action or no further action RODs, monitored natural attenuation (MNA), and institutional controls (ICs) impact five-year reviews.

1.1 What is the purpose of a five-year review?

The purpose of a five-year review is to evaluate the implementation and performance of a remedy in order to determine if the remedy is or will be protective of human health and the environment. Protectiveness is generally defined in the National Contingency Plan (NCP) by the risk range and the hazard index (HI). Evaluation of the remedy and the determination of protectiveness should be based on and sufficiently supported by data and observations.

1.2 When are five-year reviews required or appropriate?

Five-year reviews should be conducted either to meet the statutory mandate under CERCLA §121(c) or as a matter of EPA policy. Consequently, five-year reviews are classified in this guidance as either "statutory" or "policy." The Five-Year Review requirement applies to all remedial actions selected under CERCLA §121. Regions may also conduct other five-year reviews at their discretion.

You should consider a number of factors when determining whether to conduct a five-year review, as discussed in the following two sections (see Sections 1.2.1 and 1.2.2). In general, five-year reviews are required whenever a remedial action results in hazardous substances, pollutants, or contaminants remaining on site. Under the Agency's interpretation contained in the NCP, the requirement in CERCLA §121(c) is triggered when remaining on-site hazardous substances, pollutants, or contaminants are above levels that allow for "unlimited use and unrestricted exposure." See 40 CFR §300.430(f)(4)(ii).

CERCLA §121(c) states the following:

> *If the President selects a remedial action that results in any hazardous substances, pollutants, or contaminants remaining at the site, the President shall review such remedial action no less often than each five years after the initiation*

of such remedial action to assure that human health and the environment are being protected by the remedial action being implemented. In addition, if upon such review it is the judgment of the President that action is appropriate at such site in accordance with section [104] or [106], the President shall take or require such action. The President shall report to the Congress a list of facilities for which such review is required, the results of all such reviews, and any actions taken as a result of such reviews.

The Agency interpreted this requirement further in the National Contingency Plan (NCP) (40 CFR §300.430(f)(4)(ii)) which states:

If a remedial action is selected that results in hazardous substances, pollutants, or contaminants remaining at the site above levels that allow for unlimited use and unrestricted exposure, the lead agency shall review such action no less often than every five years after the initiation of the selected remedial action.

"Unlimited use and unrestricted exposure" (UU/UE) means that the selected remedy will place no restrictions on the potential use of land or other natural resources. In general, if the selected remedy relies on restrictions of land and/or groundwater use by humans and/or ecological populations to be protective, then the use has been limited and a five-year review should be conducted. For example, if a site is cleaned up to an industrial-use level, and/or other types of uses are restricted (*e.g.*, residential use), then, generally, UU/UE is not met. Exhibit 1-1, "Types of Actions Subject to Five-Year Reviews," provides examples of the types of remedial actions subject to statutory and policy reviews.

1.2.1 When is a statutory review required?

CERCLA requires five-year reviews if both of the following conditions are true:

- Upon completion of the remedial action, hazardous substances, pollutants, or contaminants will remain on site[1]; and
- The ROD for the site was signed on or after October 17, 1986 (the effective date of SARA[2]) and the remedial action was selected under CERCLA §121.

---

[1] The general response authority of CERCLA §104(c)(4) applies to both removal and remedial actions. 104(c)(4). Also see 40 CFR §300.430(f)(4)(ii).

[2] Generally, SARA became effective the date it was passed (October 17, 1986). See Pub. L. 99-499, Oct. 17, 1986, 100 Stat. 1672.

Exhibit 1-1: Types of Actions Subject to Five-Year Reviews

If the action/site is . . .	then a review is . . .	and examples of actions or components of actions include . . .
a ***post-SARA*** remedial action that, upon completion, will leave hazardous substances, pollutants, or contaminants on site above levels that allow for unlimited use and unrestricted exposure	required by ***statute***	– waste stabilization, fixation, or encapsulation on site – landfill cap or covers and slurry walls – institutional controls – sediment capping
a ***pre- or post-SARA*** remedial action that, upon completion, will not leave hazardous substances, pollutants, or contaminants on site above levels that allow for unlimited use and unrestricted exposure, **but requires five or more years to complete**	conducted as a matter of EPA ***policy***, until cleanup levels are achieved, allowing unlimited use and unrestricted exposure	– long-term monitored natural attenuation – long-term groundwater pump and treatment – long-term bioremediation of groundwater or soil – other long-term remedies, such as soil washing and land farming – monitored natural recovery (sediments)
a ***pre-SARA*** remedial action that will leave hazardous substances, pollutants, or contaminants on site above levels that allow for unlimited use and unrestricted exposure	conducted as a matter of EPA ***policy***	– waste stabilization, fixation, or encapsulation on site – landfill cap or covers and slurry walls – institutional controls
a ***removal*** **action that takes place at a site on *the NPL*** that leaves hazardous substances, pollutants, or contaminants on site above levels that allow for unlimited use and unrestricted exposure and **where no remedial action has or will take place**	conducted as a matter of EPA ***policy***	– excavation and treatment where hazardous substances, pollutants, or contaminants remain on site above levels that allow for unlimited use and unrestricted exposure

1.2.2 When is a policy review appropriate?

Five-year reviews generally should be conducted as a matter of policy for the following types of actions:

- A pre- or post-SARA remedial action that, upon completion, will not leave hazardous substances, pollutants, or contaminants on site above levels that allow for unlimited use and unrestricted exposure, but requires five years or more to complete;
- A pre-SARA remedial action that leaves hazardous substances, pollutants, or contaminants on site above levels that allow for unlimited use and unrestricted exposure; or

- A removal-only site on the NPL where a removal action leaves hazardous substances, pollutants, or contaminants on site above levels that allow for unlimited use and unrestricted exposure and where no remedial action has or will take place.

1.2.3 When should five-year reviews be completed?

The first five-year review generally should be completed and signed by the EPA Region within five years of the initial trigger date (see Sections 1.3.1 and 1.3.2). As a matter of policy, you should complete subsequent statutory or policy five-year reviews no later than five years following the signature date of the previous Five-Year Review report. Five-year reviews may be conducted earlier or more frequently than every five years, if needed, to ensure the protection of human health and the environment.

1.2.4 When can five-year reviews be discontinued?

Five-year reviews may no longer be needed when no hazardous substances, pollutants, or contaminants remain on site above levels that allow for unlimited use and unrestricted exposure. The basis for this finding should be documented in your final Five-Year Review report. When you make this determination prior to the first five-year review, you should record it in a document subject to public comment, such as a Proposed Plan or a Notice of Intent to Delete. When notice of five-year review discontinuation is given in a document other than a Five-Year Review report, the Region should submit a memorandum, signed by the Regional Administrator or his/her designee, to Headquarters. The memorandum should provide the reason for not conducting five-year reviews and cite the document in which this decision was made and supported.

1.3 When does the five-year review period begin?

The initiation or trigger date that starts the five-year review period depends upon whether the review is categorized as statutory or policy. However, the review should be completed within 5 years of its trigger date regardless of its category. Lead agencies may choose to conduct a five-year review earlier, or more frequently, than every five years to ensure the protection of human health and the environment. A discussion of the first and subsequent triggers for both statutory and policy review is provided below.

1.3.1 What actions first trigger a statutory review?

In accordance with CERCLA §121 and the NCP, a statutory review is triggered by the initiation of the first remedial action that leaves hazardous substances, pollutants, or contaminants on site above levels that allow for unlimited use and unrestricted exposure. In cases where there are multiple remedial actions, the earliest remedial action that leaves hazardous

substances, pollutants, or contaminants on site should trigger the initial review, even if it is an interim remedial action.

For the purpose of a five-year review, a remedial action typically is initiated on the date of "actual RA on-site construction" or the "actual RA start" date for Federal facilities. The date of actual RA on-site construction generally corresponds to the date the contractor begins work at a site for the remedial action, typically the date of on-site mobilization. The definition of the "actual RA start" varies as outlined in the Superfund/Oil Program Implementation Manual (SPIM). For remedies where on-site mobilization may not occur, as a matter of policy, the date of the first monitoring event following ROD signature or the ROD signature itself should be used to trigger the five-year review period.

1.3.2 What actions first trigger a policy review?

A policy review initially should be triggered by the date that construction is completed at a site. The date of construction completion is generally the date of the Preliminary Close Out Report (PCOR) or the date of the Final Close Out Report (FCOR) for sites that do not have a PCOR. The PCOR or FCOR date also triggers the initial five-year review at NPL removal-only sites.

1.3.3 What are triggers for subsequent statutory and policy reviews?

After completion of the first statutory or policy five-year review, the trigger for subsequent reviews is the signature date of the previous Five-Year Review report. For reviews led by other Federal agencies, States, or Tribes, and where EPA has a concurrence role, the trigger for subsequent reviews corresponds to EPA's concurrence signature date of the preceding Five-Year Review report (see Sections 3.7.2 and 3.7.3).

1.4 How do five-year reviews apply to a site with multiple operable units?

Five-year reviews for sites with multiple OUs, as a matter of policy, should address all OUs and remedial actions that have been initiated at the time of the review, except for situations as described in Section 1.4.2. At the Regions' discretion, the five-year review may also include and consider areas of a site where no remedial action has been selected or initiated.

1.4.1 How is a multiple operable unit site categorized?

Five-year reviews for multiple OU sites can be categorized as either statutory or policy. As a matter of policy, a site is subject to a statutory review if any one of its initiated remedial actions is subject to a statutory review. A site is subject to a policy review if no initiated actions are subject to a statutory review and at least one action is subject to a policy review.

1.4.2 When is it appropriate to conduct a separate five-year review for different areas of a large and complex site?

At some large and complex sites, individual OUs, or groups of OUs, may have been treated as separate sites throughout the remedial process. Under these circumstances, Regions may continue to treat these areas separately and conduct individual five-year reviews for each area. Each five-year review should include the status and protectiveness determination of the five-year reviews conducted for the other areas of the entire site. Regions may choose to combine the separate reviews of different areas into a single five-year review prior to, or following, construction completion for the entire site. However, no area should be reviewed later than five years after its trigger date or previous review.

Actions within each area may trigger its respective statutory or policy review. However, in cases where site-wide construction completion will not be achieved for an extended period of time, the initial trigger date for a policy review should correspond to the date that physical construction is complete at the area under consideration. The Region should establish this date on a site-specific basis which should be based on the signature date of the Interim or Final RA Report.

1.4.3 How is a site with pre- and post-SARA RODs categorized?

At sites where there are both pre- and post-SARA RODs, the pre-SARA remedial actions are subject under this policy to post-SARA Five-Year Review procedures. For example, suppose a pre-SARA remedial action initially is subject to a policy review because hazardous substances, pollutants, or contaminants are permanently left on site above levels that allow for unrestricted use and unlimited exposure. If a post-SARA ROD is signed for that same site, a five-year review should be conducted, unless the post-SARA ROD selects a remedy that removes all on site hazardous substances, pollutants, or contaminants including the hazardous substances, pollutants, or contaminants left on site by the pre-SARA action. In such cases, the original five-year review schedule should be maintained as a matter of policy. If no schedule has been established, the post-SARA trigger should be utilized.

1.5 What are some other considerations for five-year reviews?

This section discusses other considerations (*i.e.*, deletions, RCRA responses, interim and early remedial actions, no action or no further action RODs, monitored natural attenuation, and institutional controls) that may affect the need for and conduct of five-year reviews.

1.5.1 Are five-year reviews required for a site that has been deleted or partially deleted from the NPL?

It is EPA's policy that the Five-Year Review requirement is independent of and unaffected by the deletion process.[3] Consistent with the NCP, a site can be deleted or partially deleted from the NPL once the deletion criteria have been satisfied. If a site has been deleted or is in the process of being deleted, your Five-Year Review report should address the status of any deletion action. Five-year reviews continue as needed after deletion.

1.5.2 Are five-year reviews required for a site with a RCRA response?

In 1996, EPA established a policy to defer some CERCLA cleanup activities to the RCRA program. The policy is outlined in the memorandum "Coordination Between RCRA Corrective Action and Closure and CERCLA Site Activities."[4] This policy allows site managers to defer cleanup activities for all or part of a site from CERCLA to RCRA (or vice versa). If a site is deferred to RCRA prior to being placed on the NPL, or is deleted from the NPL prior to the selection of the remedy and deferred to RCRA for corrective action, you do not need to conduct a five-year review.

In cases where full deferral is not appropriate, it is possible that both RCRA and CERCLA authorities will be used to address a site. When a RCRA action is included as a part of a CERCLA action, the RCRA action should be included in the five-year review as a matter of policy, if a five-year review is required or appropriate.

1.5.3 How is a site that has an interim or early remedial action handled?

Regions should conduct five-year reviews for interim or early actions selected under CERCLA §121 consistent with Section 1.2 of this guidance.[5] For instance, Regions should conduct a review if an alternate water supply is installed and hazardous substances, pollutants, or contaminants remain on site above levels that allow for unlimited use and unrestricted exposure. If a subsequent action reduces the hazardous substances, pollutants, or contaminants on site to

---

[3] In 1991, EPA clarified its policy on whether a site deleted from the NPL is subject to a five-year review. See "Notice of Policy Change," 56 FR 66601 (December 24, 1991). In appropriate circumstances, a site does not need to be kept on the NPL solely for the purposes of conducting five-year reviews (See 55 Fed Reg at p. 8699).

[4] The memorandum "Coordination Between RCRA Corrective Action and Closure and CERCLA Site Activities" was issued by Steven A. Herman, Assistant Administrator, Office of Enforcement and Compliance Assurance, and Elliott P. Laws, Assistant Administrator, OSWER (September 24, 1996).

[5] Interim and Early actions are defined in Chapter 8 in *A Guide to Preparing Superfund Proposed Plans, Records of Decision, and other Remedy Selection Decision Documents*. EPA 540-R-98-031, OSWER 9200.1-23P (July 1999)

levels that allow unlimited use and unrestricted exposure, then reviews may be discontinued (see Section 1.2.4).

1.5.4 How is a site that has a no action or a no further action ROD handled?

Consistent with Section 1.2, Regions should conduct a five-year review for a remedy where a no action or no further action ROD leaves hazardous substances, pollutants, or contaminants on site above levels that allow for unlimited use and unrestricted exposure. For example, as a matter of policy Regions should conduct a review for an NPL site with a no action ROD where a removal-only action leaves hazardous substances, pollutants, or contaminants on site above levels that allow for unlimited use and unrestricted exposure, or where groundwater monitoring or other types of monitoring of contamination above action levels is the only remedial action selected. However, no five-year review may be needed when monitoring is used only to verify absence of contamination.

1.5.5 How is a ROD that includes monitored natural attenuation handled?

CERCLA §121 remedies relying on monitored natural attenuation or natural attenuation may be subject to five-year reviews consistent with Section 1.2. If monitored natural attenuation is included in a no action or a no further action ROD, then that ROD is not considered to be no action or no further action and therefore, Regions may need to conduct a five-year review, consistent with this guidance.

1.5.6 How is a ROD that includes institutional controls handled?

Institutional controls may be part of remedies selected under CERCLA §121 and consistent with Section 1.2 of this guidance may be subject to five-year reviews.[6] If institutional controls are included in a no action or a no further action ROD, and protectiveness relies on the institutional control, then that ROD is not considered to be no action or no further action and therefore, Regions may need to conduct a five-year review.

[6] Regions should refer to OSWER 9355.0-74FS-P, dated September 2000, entitled *Institutional Controls: A Site Manager's Guide to identifying, evaluating and selecting Institutional Controls at Superfund and RCRA Corrective Action Cleanups* for further information on institutional controls and remedy selection.

2.0 ROLES AND RESPONSIBILITIES FOR EPA, STATES, TRIBES, AND OTHER FEDERAL AGENCIES

This chapter discusses the roles and responsibilities of U.S. Environmental Protection Agency (EPA), other Federal agencies, State agencies, and Tribes, in conducting five-year reviews. As a general matter, for remedies selected under Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) §121, except at non-NPL Federal facility sites, EPA has the ultimate authority for determining whether a remedy subject to the Five-Year Review requirements in CERCLA §121(c) is protective. The National Oil and Hazardous Substances Pollution Contingency Plan (NCP) addresses, in general, the involvement of State agencies and Tribes in CERCLA actions in 40 CFR §300.515 and §300.520. Finally, CERCLA §120 and Executive Order (EO) 12580[7] address the responsibilities of Federal agencies in carrying out CERCLA cleanups.[8]

2.1 What are the roles of the lead and support agencies?

Under the NCP, the lead agency provides for the remedial project manager (RPM) "to plan and implement [the] response action;"[9] a response action would include conducting a five-year review. A support agency "furnish[es] necessary data to the lead agency, reviews response data and documents, and provides other assistance."[10] The NCP also encourages appropriate State and Tribal involvement for Fund-financed and Enforcement-lead remedial actions (see 40 CFR §300.515 and §300.520). Where the State or Tribe is the lead agency, the NCP provides that EPA concurrence is needed on remedy selection decisions (see 40 CFR §300.515(e) and §300.520).

The relative roles and responsibilities for lead and support agencies can vary significantly depending on ability, resources, and legal authorities. There are a number of documents that can be used to specify roles and responsibilities of lead and support agencies. Some of these are general in scope, while others are more narrow in scope and apply solely to a specific site. General instruments include Superfund Memoranda of Agreement (SMOAs), Cooperative Agreements (CAs), and Superfund State Contracts (SSCs). Normally, SMOAs are general, non-site-specific agreements that EPA uses to define roles and interactions in conducting a response action. EPA uses CAs to transfer Superfund monies to States or Tribes for response activities. SSCs are used to identify EPA and State or Tribal roles and responsibilities required under

---

[7]Executive Order No. 12580 of January 23, 1987, as amended on August 28, 1996.

[8]As discussed in section 2.4, State enforcement-lead cleanups are not subject to this guidance.

[9]See 40 CFR §300.5.

[10]Id.

CERCLA §104. Site-specific agreements include Consent Decrees, Administrative Orders on Consent, and Federal Facility Agreements (FFAs). If no SMOA, SSC, or CA is available, a letter of agreement should be written to define roles and responsibilities for the five-year review, consistent with the NCP (see 40 CFR §300.515). Wherever possible, the specific roles and responsibilities regarding the conduct of a five-year review should be detailed in a single document to avoid confusion and disputes at a later date.

2.1.1 What are the roles of the lead agency?

The lead agency conducts the five-year review, prepares the Five-Year Review report, and submits the report to the support agency for review and comment. The lead agency is also responsible for conducting community involvement activities and for ensuring that recommendations and follow-up actions identified during five-year reviews are completed. Generally, funding for five-year reviews is provided by EPA for Fund-financed sites, Potentially Responsible Parties (PRPs) for Enforcement-lead sites (through appropriate mechanisms), and by other Federal agencies or departments for Federal facility sites.

Where EPA is the lead agency pursuant to 40 CFR §300.515, the Region should submit a copy of its final Five-Year Review report to EPA Headquarters (HQ) within 10 days of signature, and provide copies to the support agency and site information repositories. Where the State or Tribe is the lead agency, pursuant to 40 CFR §300.515, the State should submit a copy of the final Five-Year Review report to the Region; once the Region has concurred, the Region should provide a copy to EPA HQ within 10 days of signature, to any other support agencies, and to site information repositories. Where another Federal agency or department is the lead agency, pursuant to CERCLA §120 and EO 12580, the Federal agency or department should submit a copy of the final Five-Year Review report to the Region; once the Region has concurred, the Region should provide a copy to HQ within 10 days of signature, to any other support agencies, and to site information repositories.

2.1.2 What are the roles of the support agency?

The role of the support agency is to participate in the review process, if requested, and review and comment on the Five-Year Review report. Where the State or Tribe is the lead agency for a response action (such as conducting a five-year review), the NCP provides that it must obtain EPA's concurrence (see 40 CFR §300.515(e)).

The lead agency should give the support agency an adequate opportunity to participate in the five-year review process and to review and comment on the draft Five-Year Review report before it is finalized. When there is more than one support agency involved, time allowances for review and comment should be the same for all support agencies who choose to participate in the review process. The amount of time that a support agency will have to review the Five-Year Review report should be documented in the SMOA, SSC, CA, or other agreement documents,

but should not be less than review times for other remedy decision documents (see 40 CFR §300.515(h)(3)). The goal should be to resolve any concerns of support agencies before drafting the final report. In any case, the support agency or agencies may provide written comments on the Five-Year Review report. Lead and support agencies should work together throughout the five-year review process to ensure that concerns are resolved in a timely manner, and to the extent practicable, prior to finalizing the Five-Year Review report.

2.2 Who conducts the review at a Fund-financed site?

At Fund-financed sites, the ultimate responsibility for the protectiveness determination rests with EPA. As described in Section 2.1, EPA may be the lead or support agency.

Regions may acquire the services of a contractor or establish agreements with other agencies (*e.g.*, the U.S. Army Corps of Engineers) to perform studies, conduct investigations, and/or develop draft Five-Year Review reports. In all cases, Regions should ensure the quality and completeness of review activities and the content of the final Five-Year Review report.

2.3 What if a site is an Enforcement-lead site?

At CERCLA Enforcement-lead sites, the ultimate responsibility for the quality and completeness of review activities and the content and protectiveness determinations of the Five-Year Review report rests with EPA. As described in Section 2.1, EPA may be the lead or support agency.

At sites in which EPA is the lead agency Regions may acquire the services of a contractor or establish agreements with other agencies (*e.g.*, the U.S. Army Corps of Engineers) to perform studies, conduct investigations, and/or develop draft Five-Year Review reports.

PRPs or PRP-hired contractors may perform certain support activities (*e.g.*, data collection, studies or analysis) according to provisions of an enforceable agreement.

2.4 What if site activities are led by a State or Tribe?

As described in Section 2.1, States and Tribes can be the lead agency in carrying out a five-year review. In those cases, States or Tribes should ensure the quality and completeness of review activities and the content of the final Five-Year Review report, prior to submitting the report to the Region for EPA's concurrence. When a State or Tribe provides EPA with a Five-Year Review report, EPA can choose to concur with the report and protectiveness statements or make its own protectiveness determinations.

Where a State or Tribe conducts a cleanup using its own legal authorities (*e.g.*, State enforcement action under a CERCLA-equivalent State law), the remedy is not selected pursuant to CERCLA §121 and is not subject to the Five-Year Review requirement.

Exhibit 2-1 provides an overview of the typical roles of different parties for each type of response action.

Exhibit 2-1: Typical Roles in the Five-Year Review Process*

If the response action is...	at...	under...	then conducting the review is the responsibility of...	with funding by...	and with the EPA Region...
Fund-financed	a site	CERCLA §121,and CERCLA §104	the lead agency; when the lead agency is a State or Tribe, EPA concurs;	Superfund	making or concurring with the protectiveness determination.
Enforcement -lead	a site	CERCLA §104 and §121, along with a Consent Decree or other enforcement document	the lead agency; when the lead agency is a State or Tribe, EPA concurs. (PRPs may be allowed to provide certain support for five-year reviews);	PRPs	making or concurring with the protectiveness determination.
Other Federal agency or department (*e.g.*, led by Department of Defense, Department of Energy or Department of the Interior)	a Federal facility NPL site	CERCLA §104, §120 and §121, Executive Order 12580, and a Federal Facility Agreement	the respective Federal agency or department	the respective Federal agency or department	making or concurring with the protectiveness determination.
Other Federal agency	a Federal facility non-NPL site	CERCLA §104 and §121, and Executive Order 12580	the respective Federal agency or department	the respective Federal agency or department	commenting on the protectiveness determination (if requested).

Note: * The scenarios presented in the exhibit are not all inclusive. Regions should determine the respective roles in the five-year review process when other circumstances exist. EPA does not have a role in five-year reviews at non-NPL Federal facility sites; however, EPA Regions may comment or be asked to comment on a site-specific basis.

2.5 What if site activities are led by another Federal agency or department?

CERCLA §104, §120, and §121 identify functions and responsibilities vested in the President for undertaking response efforts and coordinating all other efforts at the scene of a

release on or from Federally-owned property (or vessels). The President, in EO 12580, delegates some of these responsibilities to the respective Federal agencies and departments for Federally-owned or Federally-operated facilities over which these lead agencies have jurisdiction, custody, or control.

Therefore, at sites where activities are led by another Federal agency or department, the Federal agency or department has responsibilities for selecting remedies and implementing the remedial actions, and for conducting all required five-year reviews. The Federal agency or department is responsible for planning, coordinating, funding, and conducting five-year reviews and for making protectiveness determinations upon conclusion of each five-year review. Federal agencies or departments are encouraged to have EPA, States, and Tribes participate and comment throughout the five-year review process, as appropriate. Federal agencies or departments are also responsible for initiating resolutions to issues and following up on all recommendations that result from these five-year reviews. Federal agencies or departments may not adopt or utilize guidelines that are inconsistent with EPA's Five-Year Review guidance or certain other EPA guidance, as specified in CERCLA §120(a)(2).

- ***Federal facility sites that are listed on the NPL*** – EO 12580 paragraphs 2(d) and (g) delegate remedial responsibilities to the Department of Defense (DOD) and the Department of Energy (DOE), and to EPA, respectively. In addition, at all Federal facility NPL sites, CERCLA §120 requires Federal agencies or departments to perform remedial investigation and feasability studies (RI/FS) (see CERCLA §120(e)(1)), to enter into Inter-Agency Agreements (IAGs) (frequently called Federal Facility Agreements), and to initiate remedial actions, subject to EPA concurrence. Therefore, five-year reviews are conducted by the Federal agency or department that has jurisdiction, custody, or control, but EPA retains final authority over whether the five-year reviews adequately address the protectiveness of remedies. EPA will either concur with the final Federal agency or department protectiveness determination, or EPA may provide independent findings. Disputes which arise related to protectiveness determinations or independent findings by EPA may be resolved on a site-specific basis through formal dispute resolution procedures, typically established in FFAs. Exhibits 2-2 and 2-3 and Sections 2.5.1 and 2.5.2 discuss Federal facility NPL sites and FFAs in more detail.

- ***Non-NPL Federal facilities*** – EO 12580, paragraphs 2(d) and (e), give remedial responsibilities, and therefore five-year review responsibilities, to the Federal agency or department having jurisdiction, custody, or control. EPA may also be asked to comment, to the extent practical, on five-year reviews or protectiveness determinations at non-NPL Federal facilities. Section 2.5.3 discusses non-NPL Federal facilities in more detail.

Exhibit 2-2 below provides an overview of relevant EO 12580 sections and their applicability.

Exhibit 2-2: Federal Responsibilities Under Executive Order 12580

In EO 12580 section(s)...	the President delegates to...	certain remedial functions and responsibilities in CERCLA section(s)...	and those remedial functions and responsibilities at Federal facilities generally pertaining to...
2(b)	***EPA*** (in consultation with the National Response Team)	121(f)(1)	promulgation of regulations assuring substantial and meaningful State involvement (in initiation, development, and selection of remedial actions to be undertaken in the State).
2(d)	***DOD, DOE,*** (subject to the requirements described in CERCLA §120)	104(a), 104(b), 104(c)(4), and 121	selecting and taking NPL and non-NPL[1] [2] remedial actions, which includes both conducting five-year reviews and making protectiveness determinations (with EPA concurrence at NPL sites).
2(e)	***Federal Departments/ Agencies*** (for non-NPL Federal facility sites.)	104(a), 104(b), 104(c)(4), and 121	selecting and taking non-NPL remedial actions, which includes both conducting five-year reviews and making protectiveness determinations.
2(g)	***EPA*** (subject to the above delegations)	104(a), 104(b), 104(c)(4), and 121	selecting and taking NPL remedial actions, which includes conducting five-year reviews and making protectiveness determinations at Fund-lead and Enforcement-lead NPL sites.

Note: [1] EPA does not have a role in five-year reviews at non-NPL Federal facility sites; however, EPA Regions may be asked to comment on a site-specific basis.

[2] In addition to the EO 12580 delegation of remedy selection and remedial action responsibilities to all Federal agencies and departments for non-NPL Federal facility sites, CERCLA §120(e) establishes remedy selection and remedial action responsibilities for Federal agencies and departments for all Federal facility NPL sites, as well. For example, CERCLA §120(e)(2) requires Federal agencies and departments to enter into NPL IAGs (frequently called FFAs) with EPA (States may participate.) CERCLA §120(e)(4) requires FFAs to address selection of remedies and completion of remedial actions at Federal facility NPL sites. FFAs, where applicable, should specify the procedures to be followed with respect to conducting five-year reviews at Federal facility NPL sites.

The following subsections detail responsibilities for conducting five-year reviews at sites led by other Federal departments and agencies.

2.5.1 What is the purpose of FFAs at other Federal agency NPL sites?

CERCLA §120(e)(2) requires that EPA sign an IAG (frequently called an FFA) with responsible Federal agencies or departments to detail respective roles and responsibilities for remedial actions at NPL sites. CERCLA §120(e)(1) requires Federal agencies or departments to conduct remedial investigations in consultation with EPA and appropriate State authorities at Federal facility NPL sites. Most Federal facility NPL sites will have site-specific roles and responsibilities specified in the FFA. CERCLA §120(e)(4) requires FFAs to include selection of remedies, completion of remedial actions, and arrangements for long-term operation and maintenance of the facility. Therefore, the procedures for conducting five-year reviews and making protectiveness determinations fall within the scope of FFAs. FFAs should specify in detail the procedures governing five-year reviews at Federal facility NPL sites.

OSWER Directive 9320.0-75 (November 29, 1996), "Federal Facilities Streamlined Oversight Directive" reiterates EPA's responsibility for oversight of remedial activities at Federal facility NPL sites. States and Tribes, as regulators, may also have an oversight role, defined in the FFA, at a facility. Exhibit 2-3 describes the topics to be addressed in an FFA.

Exhibit 2-3: Federal Facility Agreements and Five-Year Reviews

CERCLA § 120(e)(2) requires that the relevant Federal agency or department must enter into an FFA (IAG in the statute) with EPA within six months after EPA's review of the Remedial Investigation/Feasibility Study (RI/FS) is completed. States may be signatories to the FFA and under CERCLA §120 (f) must be included in the decision-making process at Federal facility NPL sites. Whenever a Federal facility is located on Tribal lands, the appropriate Tribal government should be involved.

CERCLA §120(e)(4), in the case of schedules, requires that the EPA/DOD and EPA/DOE Model FFA contain procedures for the submission and review of documents, schedules of cleanup activities, and provisions for dispute resolution. Regions should examine FFAs with respect to the performance of five-year reviews to clarify:

- Roles, responsibilities, and milestones;
- Arrangements for long-term operation and maintenance of the facility; and
- Opportunities for public involvement.

For Federal facilities only, EPA considers Five-Year Review reports to be stand-alone primary documents or part of another related primary document that should have an enforceable schedule within the framework of the FFA. Where EPA enters into an FFA, the agreement should include all site-specific Five-Year Review requirements, such as provisions for reviews, public participation, and addressing or resolving issues.

Where the roles and responsibilities for conducting five-year reviews and making protectiveness determinations are not specified in an FFA (for example, the FFA may not have been signed, or it may be silent or unclear with respect to five-year reviews), then the parties should rely on this guidance for fulfilling EPA's obligations under CERCLA §120 and §121, including making protectiveness determinations. Five-year review requirements should be

identified early in the FFA process, so that the parties to the Agreement have clearly defined roles and responsibilities for implementing CERCLA §121(c) with respect to five-year reviews. However, consistent with CERCLA §120(g), FFAs cannot re-delegate EPA's final authority over whether the five-year reviews adequately address the protectiveness of remedies.

2.5.2 What is EPA's role at NPL sites under the jurisdiction of another Federal agency or department?

CERCLA §120 and EO 12580 provide the basis for EPA's oversight role at other Federal agency NPL sites. This role includes the following:

- Assisting in the determination of cleanup remedies or potentially selecting the remedies, in consultation with the lead agency and appropriate State authorities, beginning at the commencement of remedial investigations and feasibility studies;
- Ensuring that Federal agencies or departments appropriately consider all relevant guidance and policies that EPA determines are appropriate;
- Ensuring compliance with signed FFAs; and
- Determining that decisions protect human health and the environment and that such decisions are adequately supported in the Five-Year Review report (whether as a stand-alone primary document or part of a related primary document).

EPA is not responsible for conducting five-year reviews at Federal facility NPL sites. However, EPA's final remedy selection authority at Federal facility NPL sites requires that EPA retain final authority to make protectiveness determinations. Accordingly, EPA will either concur with any protectiveness determinations to ensure protection of human health and the environment, consistent with EPA's statutory and regulatory authorities or EPA may provide independent findings. EPA Regions should review Federal facility NPL Five-Year Review reports (whether as a stand-alone primary document or part of a related primary document) and protectiveness determinations for consistency with this guidance and adequacy of the supporting basis, and should participate or comment throughout the five-year review process, as appropriate.

2.5.3 What is EPA's role at a non-NPL site under the jurisdiction of another Federal agency or department?

EO 12580 paragraphs 2(d) and (e)(1) delegates the authority in CERCLA §104 and §121 to the Federal agencies or departments for selecting and conducting remedial actions addressing releases or threatened releases at sites that are not on the NPL. Consistent with CERCLA §121 and this guidance, Federal agencies or departments should conduct five-year reviews for all CERCLA non-NPL remedial actions that require a review (discussed in Section 1.2.1 of this

guidance). It is EPA's expectation that Federal agencies or departments will also conduct five-year reviews as a matter of policy at sites that would be subject to policy reviews if they were on the NPL (see Section 1.2.2). EPA does not have a statutorily defined role in five-year reviews at non-NPL Federal facility sites. However, where EPA has had active and substantial involvement at a non-NPL Federal facility, or where agencies, States, Tribes, or citizens seek EPA comment on five-year reviews conducted at a non-NPL Federal facility, EPA may, to the extent practicable on a site-specific basis, comment on five-year reviews and protectiveness determinations made by other Federal agencies or departments at non-NPL Federal facilities, and/or provide independent findings, where applicable.

2.5.4 What are States' roles at non-NPL sites under the jurisdiction of a Federal agency or department?

Consistent with CERCLA §120(a)(4), at non-NPL Federal facilities sites, States generally have remedial oversight responsibilities and should be provided with adequate opportunity to participate in the five-year review process and to review the draft Five-Year Review document before it is finalized.

2.5.5 What happens when Federal agencies or departments transfer real property?

In instances of Federal-to-Federal transfer of jurisdiction, custody, or control of real property, the Federal agency or department having initiated CERCLA remedial actions generally should conduct any required or appropriate five-year reviews. Alternatively, the lead agency may assure that reviews are conducted by entering into reliable site-specific agreements with the Federal agency or department gaining control of the property, where those arrangements remain consistent with CERCLA and EO 12580. In instances of deed transfer of Federal property to third parties, the Federal agency or department having initiated CERCLA remedial actions generally should conduct any required or appropriate five-year reviews, unless other reliable site-specific procedures are arranged with the transferee (or others), and those arrangements remain consistent with CERCLA and EO 12580. Generally, however, the ultimate responsibility for conducting five-year reviews should remain with the Federal agency or department that initiated the CERCLA remedial actions.

[This page intentionally left blank.]

3.0 COMPONENTS OF THE FIVE-YEAR REVIEW PROCESS

This chapter discusses components of the five-year review process, including notifying potentially interested parties, developing a review schedule, establishing a review team, involving the community, and signing and submitting the Five-Year Review report. Data and other site-specific information that form the foundation for the technical assessment of the remedy at the time of the five-year review are discussed in this chapter, including data and document review, site interview, site inspection, and components of a Five-Year Review report.

3.1 Who is notified when planning the five-year review?

In the initial planning stages of the five-year review, all potentially interested parties should be notified that the five-year review will be conducted. This notification may include States and/or Tribes, appropriate representatives of the community, local officials, Federal and/or State Trustees for Natural Resources (Trustees)[11], appropriate EPA offices, and the Community Involvement Coordinator (CIC) for the site. Potentially responsible parties should be notified for Enforcement-lead sites.

3.2 How should I develop a review schedule?

You should develop a review schedule to meet the appropriate five-year review date of completion. The review schedule should allow sufficient time for each component of the five-year review process, including document review, site inspection, interviews, the assessment of the protectiveness of the remedy (see Chapter 4), and report development and final submission. You should incorporate into the five-year review schedule appropriate time for internal and inter-agency review and comment periods, community involvement activities, if needed, and finalizing the report with all required signatures.

3.3 How should I establish a review team?

You should determine the appropriate level of assistance and team structure. For some reviews, the project manager may be the only member of the team, consulting with technical experts as necessary. For other reviews, a multi-disciplinary team may be needed to adequately review the protectiveness of the remedy. Once team members are identified their roles should be clearly defined. Communication among team members, agencies, and organizations is critical to ensure that all parties remain informed throughout the entire five-year review process.

---

[11] OSWER Directive 9200.4-22A *CERCLA Coordination with Natural Resource Trustees*, dated July 31, 1997.

Exhibit 3-1 below provides examples of potential team members for a five-year review.

Exhibit 3-1: Potential Members of the Five-Year Review Team

- Project Manager (EPA, State, Tribal, DOD, DOI)
- Regional Biological Technical Assistance Groups (BTAGs)
- Federal and State Natural Resource Trustees
- Community Involvement Coordinator (CIC)
- State and/or local regulatory agency representatives
- Tribal representatives
- TAG representatives and/or community representatives
- Other Federal agency representatives (*e.g.*, U.S. Army Corps of Engineers, U.S. Fish and Wildlife Service, Agency for Toxic Substances and Disease Registry, U.S. Geological Survey, National Oceanic and Atmospheric Administration)
- Technical Experts
  - Construction representative
  - Engineers (*e.g.*, civil, geo-technical, structural, chemical, process)
  - Hydrogeologist
  - Chemist
  - Risk assessor
  - Biologist
  - Ecologist/ecological risk assessor
  - Attorney/legal advisor
  - Environmental regulatory specialist

3.4 How should I involve the community?

You should begin working with the site's CIC during the initial planning stages of your five-year review to determine the appropriate level of community involvement. At a minimum, your community involvement activities during the five-year review should include notifying the community that the five-year review will be conducted, notifying the community that the five-year review has been completed, and providing the results of the review to the local site repository (see Exhibit 3-2).

Together with the CIC, you should consider conducting additional community involvement activities at high profile sites, those with significant public interest, and any other sites for which the Region determines a need for additional community involvement activities. This may include notifying local public officials, including the primary local health agency, and the leadership of any relevant neighborhood and civic groups. (For ideas on notifying the public see *Publishing Effective Public Notices*, which is part of the CIC Toolkit (Web address: http://www.epa.gov/superfund/action/community/index.htm).)

In addition to this notification, you may also wish to interview several community members, at least some of whom live or work near the site, to get their views about current site conditions, problems, or related concerns. If there was or is a Community Advisory Group or a

Technical Assistance Grant related to the site, representatives of these groups should be briefed at the outset of the five-year review process, and, if requested, at other appropriate points. You may also want to consider appropriate ways, such as public meetings or an opportunity for submitting written comments, to get broader public involvement. For further information on community involvement during the five-year review process, see Appendix A, "Community Involvement."

Exhibit 3-2: Notification Requirements for Five-Year Reviews

At the beginning: Your notice to the community that a five-year review will be conducted should identify:

- The site name, its location and web address (if available);
- The lead agency conducting the review;
- A brief description of the selected remedy;
- A summary of contamination addressed by the selected remedy;
- How the community can contribute during the review process;
- A contact name and telephone number for further information; and
- The scheduled completion date of the five-year review.

At the end: Your notice to the community that a five-year review has been completed should include:

- The site name, its location and web address (if available);
- The lead agency conducting the review;
- A brief description of the selected remedy;
- A summary of contamination addressed by the selected remedy as provided in the initial notice;
- A brief summary of the results of the five-year review;
- The protectiveness statement(s);
- A brief summary of data and information that provided the basis for determining protectiveness, issues, recommendations, and follow-up actions directly related to the protectiveness of the remedy;
- Location(s) where a copy of the five-year review can be obtained or viewed (including site repositories);
- A contact name and telephone number where community members can obtain more information or ask questions about the results; and
- The date of the next five-year review or a statement and supporting rationale that five-year reviews will no longer be required.

3.5 What data do I need to evaluate the remedy?

Data and other pertinent site specific information that you should review include sampling and monitoring plans and results from monitoring activities, operation and maintenance (O&M) reports or other documentation of remedy performance, including previous Five-Year Review reports. These are the primary bases of the technical analyses and subsequent protectiveness determination(s). The type and quality of data are essential to your five-year review and its findings and conclusions. You may collect these types of data through a variety of means, including document review, interviews, and a site inspection. You also may need to conduct supplemental sampling or collect other data.

3.5.1 How are documents reviewed?

A review of documents is one of the first steps in the five-year review process. You are responsible for gathering all relevant documents, data, and other information in support of the five-year review. Generally, for an initial five-year review, this may require you to evaluate record keeping and the location of pertinent data and information. In cases where records are difficult to obtain, you should establish appropriate record keeping procedures to minimize future efforts needed to gather all necessary documents for subsequent five-year reviews.

Documents should be reviewed to obtain relevant information and data concerning a response action from which to base an assessment of its performance. The scope of the review is dependent on the complexity of the remedy(s) and the stage of remedy construction. You may need to review various documents to obtain the necessary information, including those for remedy decisions (*e.g.*, Records of Decision (RODs), Explanation of Significant Differences (ESDs)), enforcement (*e.g.*, Consent Decrees (CDs), Administrative Orders on Consent (AOCs)), site investigations (*e.g.*, remedial investigation/feasibility study (RI/FS)), design (*e.g.*, remedial design (RD)) and construction (*e.g.*, Preliminary Closeout Reports (PCOR), remedial action (RA) reports), and remedy performance and post-closure. (See Appendix B, "Document Review," for a more complete discussion of document review for the five-year review).

Your review team should be familiar with appropriate site-specific data and information including the items listed below:

- Remedial action objectives and cleanup levels, as specified in the ROD and other decision documents;
- Remedial action design and remedial action construction;
- O&M status;
- Implementation of institutional controls;
- Changes that affect the validity of cleanup levels (*e.g.*, standards identified as Applicable or Relevant and Appropriate Requirements (ARARs), "to be considereds" (TBCs), assumptions about contaminant characteristics and potential exposure); and
- Data supporting the effectiveness of the remedy in meeting cleanup levels and remedial action objectives.

3.5.2 How should I conduct interviews?

Interviews should be conducted, if necessary, to provide additional information about a site's status. The scope of interviews should be tailored to the remedy evaluation on a site-specific basis. Those interviewed may include the site manager; site personnel; Federal, State, and Tribal regulatory authorities; local officials; community action groups or associations;

residents and businesses located near the site; and other pertinent organizations or individuals. At an Enforcement-lead site, the lead agency should conduct the interviews. A Potentially Responsible Party (PRP) generally should not conduct interviews because there is a potential for a conflict of interest (see Appendix C, "Five-Year Review Interviews," for additional information). For Federal facility sites, a State and/or EPA representative may wish to be present at and/or participate in conducting interviews.

3.5.3 How should I conduct site inspections?

Your five-year review should include a recent site inspection. For purposes of conducting site inspections for five-year reviews, "recent" generally means no more than nine months from the expected signature date of the review. The review should be performed by objective parties without bias or preconceived views or conclusions about the remedy and conditions at the site. Site inspections are conducted to provide information about a site's status and to visually confirm and document the conditions of the remedy, the site, and the surrounding area.

At an Enforcement-lead site, the lead agency should conduct the site inspection. A PRP generally should not conduct the site inspection because of the potential for a conflict of interest. At Federal facility sites, a State and/or EPA representative may wish to be present and/or participate in conducting site inspections.

Appendix D, "Five-Year Review Site Inspection Checklist," may serve as your guide for planning and documenting a site inspection for containment, groundwater, and surface water remedies. Using this checklist should aid you in the planning and documentation of the site inspection. Therefore, you may adapt this checklist for other types of remedies or use other site inspection tools and checklists that have been developed by others for this purpose. You can find other checklists by accessing the web site: http://www.frtr.gov/optimization/general/ and clicking on " USACE Remediation System Evaluation Checklists."

3.6 What should I include in Five-Year Review reports?

In your Five-Year Review report, you should present the findings and conclusions of the review, including recommendations, follow-up actions to issues, and protectiveness determination(s). The report should also contain the data and information necessary to support all findings and conclusions.

Where your review only addresses a portion of a site, the report should provide a summary of the status of other operable units (OUs) and/or the remainder of the site. Similarly, for sites where you conduct a separate five-year review for different areas of a large or complex site (see Section 1.4.2), you should provide a summary of the status of the other areas of the site in your Five-Year Review report. Additionally, if you receive written comments on the Five-Year Review report from support agencies and/or the community (*e.g.*, States, Tribes, other

Federal agencies or departments, local governments, citizens, PRPs, other interested parties), you should attach a copy of these comments to the report.

A suggested "Five-Year Review Report Template" and "A Sample Five-Year Review Report" are provided in Appendices E and F, respectively. Exhibit 3-3 summarizes the recommended contents of a Five-Year Review report.

Exhibit 3-3: Contents of a Five-Year Review Report

The following report sections...	should include these topics when appropriate:
I. Introduction	– the purpose of the review – who conducted the review – when the review was initiated and completed – whether it is the first review or a subsequent review at the site – status of other five-year reviews, OUs, and/or areas of the entire site
II. Site Chronology	– dates of major events (such as the initial discovery of contamination, NPL listing, decision and enforcement documents, start and completion of remedial and removal actions, construction completion, and prior five-year reviews)
III. Background	– physical characteristics – land and resource use – history of contamination – initial response – summary of basis for taking action
IV. Remedial Actions	– remedy selection – remedy implementation – system operations/O&M
V. Progress Since Last Review (as applicable)	– protectiveness statements from last review – status of recommendations and follow-up actions from last review – results of implemented actions, including whether they achieved the intended purpose – status of any other prior issues
VI. Five-Year Review Process	– notification of potentially interested parties of start of review – identification of five-year review team members – components and schedule of your five-year review – document review – data review and evaluation – community notification – other community involvement activities – site inspection – site interviews

Exhibit 3-3: Contents of a Five-Year Review Report

The following report sections...	should include these topics when appropriate:
VII. Technical Assessment	*Question A: Is the remedy functioning as intended by the decision documents?* – remedial action performance and monitoring results – system operations/O&M – costs of system operations/O&M – opportunities for optimization – early indicators of potential remedy problems – implementation of institutional controls and other measures *Question B: Are the exposure assumptions, toxicity data, cleanup levels, and remedial action objectives (RAOs) used at the time of the remedy still valid?* – changes in exposure pathways – changes in land use – new contaminants and/or contaminant sources – remedy byproducts – changes in standards, newly promulgated standards, and TBCs – changes in toxicity and other contaminant characteristics – expected progress towards meeting RAOs – risk recalculation/assessment (as applicable) *Question C: Has any other information come to light that could call into question the protectiveness of the remedy?* – ecological risks – natural disaster impacts – any other information that could call into question the protectiveness of the remedy Summary of Technical Assessment – summary of findings and conclusions related to Questions A, B, and C
VIII. Issues	– issues that were identified during the technical assessment and other five-year review activities (*e.g.*, site inspection) – a determination of whether issues affect current or future protectiveness – a discussion of unresolved concerns or items raised by support agencies and the community (States, Tribes, other Federal agencies or departments, local governments, citizens, PRPs, other interested parties)
IX. Recommendations and Follow-up Actions	– list of any recommendations, including follow-up actions to ensure protectiveness – parties responsible for implementation – agencies with oversight authority – schedule for completion
X. Protectiveness Statement(s)	– protectiveness statement(s) developed at the OU level – protectiveness statement developed for the site as a whole at construction complete sites
XI. Next Review	– statement of when the next review is to be completed, or explanation of why no further five-year reviews are needed

3.7 How should I submit a Five-Year Review report?

The procedures for submitting reports to EPA Regions and Headquarters are described below. This process takes place after all reviews of draft reports, and other interagency reviews are completed, appropriate concurrences and signatures are obtained, and, to the extent practicable, issues are resolved.

3.7.1 How is an EPA-lead report submitted?

A report prepared by EPA is complete when it is signed by the EPA Regional Administrator or his/her designee. The Region should submit one copy of the signed Five-Year Review report to EPA Headquarters within ten days of the signature date. The Region should also place a copy of the report in each site information repository.

3.7.2 How is a Federal facility-lead report submitted?

When a Federal agency or department other than EPA conducts a five-year review, the report should be submitted to the Region for review pursuant to the terms of the Federal Facility Agreement or other authorized agreement. The Region should review the report for accuracy, protectiveness determination/statement, and the basis/support for such determination and consistency with this guidance. The EPA Regional Administrator or his/her designee should issue a memorandum that documents any unresolved items or concerns and either concurs with the report findings or provides EPA's own independent findings and protectiveness determination. Within ten days of the signature date of the memorandum, the Region should forward a copy of the report, with the memorandum attached, to EPA Headquarters, and a copy should be placed in each site information repository.

In some cases, EPA may have minimal involvement at the site or in the development of the Five-Year Review report or protectiveness statements. In such cases, Regions should determine whether to rely solely on the information presented by the other Federal agency or department without independent verification. When the Region relies solely on the representations of another Federal agency or department, the Regional Administrator or his/her designee should note this in the memorandum. It is important to consider who signed the Five-Year Review report at the other Federal agency or department. EPA expects that a Five-Year Review report generally will be signed by the other Federal agency or department at the senior management level.

3.7.3 How is a State or Tribal-lead report submitted?

When a State or Tribe conducts a five-year review, the report should be submitted to the respective Region for review of accuracy, protectiveness determination/statement and the basis/support for such determination and consistency with this guidance. The EPA Regional Administrator or his/her designee should issue a memorandum that documents any unresolved

items or concerns and either concurs with the report findings and protectiveness statement(s) or provides EPA's own independent findings and protectiveness determination. Within ten days after the memorandum is signed, the Region should forward a copy of the report, with the memorandum attached, to EPA Headquarters and a copy should be placed in each site information repository.

3.8 What are the annual reporting requirements to EPA Headquarters?

Each EPA Region should report annually to EPA Headquarters on the progress of the five-year reviews for each of their sites. At a minimum, at the end of each fiscal year each Region should provide to EPA Headquarters the following:

- A list of sites that had five-year reviews due for that fiscal year;
- If a five-year review due date changes for any site, or a site no longer needs a five-year review, identify the sites and the basis for the change or discontinuation;
- A list of those sites where five-year reviews were completed;
- For each completed five-year review, a summary of the protectiveness determination(s), issues that impact protectiveness, follow-up actions, and the schedule and entity responsible for implementing such actions;
- Status of protectiveness when Five-Year Review reports from previous fiscal years made a "not protective" determination or "needed further information" before making a protectiveness determination, or deferred protectiveness; and
- Status of follow-up actions identified in Five-Year Review reports from previous fiscal years.

The exact date for submitting the annual report should be provided at the work planning sessions at the beginning of each fiscal year or through your Headquarters Regional Center contact.

[This page intentionally left blank.]

4.0 ASSESSING THE PROTECTIVENESS OF THE REMEDY

A five-year review should determine whether the remedy at a site is or upon completion will be protective of human health and the environment. The level of effort necessary to conduct a five-year review is site-specific and should be tailored appropriately for the remedial action and its stage of implementation. In general, five-year reviews of remedial actions under construction are narrower in scope than five-year reviews of remedies that have been constructed.

Your technical assessment of a remedy should examine the following three questions, which provide a framework for organizing and evaluating data and information and ensure that all relevant issues are considered when determining the protectiveness of the remedy:

- ***Question A*** – Is the remedy functioning as intended by the decision documents?
- ***Question B*** – Are the exposure assumptions, toxicity data, cleanup levels, and remedial action objectives (RAOs) used at the time of the remedy selection still valid?
- ***Question C*** – Has any other information come to light that could call into question the protectiveness of the remedy?

The following sections present Questions A, B, and C in more detail. Exhibit 4-1 summarizes a number of items that you should consider in answering questions A, B, and C in your evaluation of a remedial action.

Exhibit 4-1: Three Questions Used to Determine Whether a Remedy is Protective

When you ask...	you should consider whether...
Question A: Is the remedy functioning as intended by the decision documents?	• performance standards (*e.g.*, cleanup levels, plume containment, pumping rates) are or will likely be met; • there are problems with the remedy that could ultimately lead to the remedy not being protective or suggest protectiveness is at risk (*e.g.*, shrubs or bushes growing on a landfill cap that was designed to have a grass vegetative cover, extent of plume not fully delineated); • access (*e.g.*, fencing, security guards) and institutional controls needed at the particular stage of the remediation are in place and prevent exposure; • other actions (*e.g.*, removals) necessary to ensure that there are no exposure pathways that could result in unacceptable risks have been implemented; and • maintenance activities (*e.g.*, pumping and treating, monitoring slurry walls, mowing cap), as implemented, will maintain the effectiveness of response actions.

Exhibit 4-1: Three Questions Used to Determine Whether a Remedy is Protective

When you ask...	you should consider whether...
Question B: Are the exposure assumptions, toxicity data, cleanup levels, and remedial action objectives used at the time of the remedy selection still valid?	• there are changes in standards identified as Applicable or Relevant and Appropriate Requirements (ARARs) in the ROD, newly promulgated standards, and/or changes in TBCs identified in the ROD, that could call into question the protectiveness of the remedy; • there are changes in land use or the anticipated land use on or near the site; • new human health or ecological exposure pathways or receptors have been identified; • new contaminants or contaminant sources have been identified; • there are unanticipated toxic byproducts of the remedy not previously addressed by the decision documents; • there are changes in the physical site conditions; and • there are changes in the toxicity factors for contaminants of concern.
Question C: Has any other information come to light that could call into question the protectiveness of the remedy?	• ecological risks have been adequately addressed at the site, and/or there is a plan to address them through a future action; and • the site is/was subject to natural disasters, such as a 100-year flood.

4.1 Question A: Is the remedy functioning as intended by the decision documents?

In general, to determine if the remedy is functioning as described in the decision documents, you should first consider its implementation status, (*e.g.*, whether the remedy is under construction, operating, or completed). You should also look for available information about the remedy and compare it to the requirements in the decision documents and remedial design/construction specifications. For purposes of this guidance, definitions of remedial actions under construction, operating remedial actions, and completed remedial actions are as follows:

- ***Remedial actions under construction*** are those actions where physical construction has been initiated, but is not yet complete.

- ***Operating remedial actions*** are those actions that are ongoing, but where cleanup levels have not yet been achieved. Such actions typically have remedial components requiring several years to reach cleanup levels (*e.g.*, groundwater and surface water restoration, monitored natural attenuation, soil vapor extraction, and bioremediation).

- ***Completed remedial actions*** are those actions where construction is complete and cleanup levels have been achieved.

4.1.1 How do I answer Question A for a remedial action that is under construction?

In the case where a remedy is under construction, the focus of your review should be to determine if the remedy is being constructed in accordance with the requirements of the decision documents and design specifications, and if the remedy is expected to be protective when it is completed. In addition, you should confirm that access controls (*e.g.*, fencing, security guards) necessary at this stage of the remediation are in place and successfully prevent exposure. If the remedial action includes institutional controls (ICs), then your five-year review should also consider the implementation status of those controls. For example, answer the following questions: Have specific ICs been identified? Are there ICs needed at this stage of remediation to prevent exposure? Who is responsible for implementing ICs? What is the plan, schedule, and current status for IC implementation?

4.1.2 How do I answer Question A for a remedial action that is operating or completed?

Your review of an operating or completed remedial action generally will address more aspects of the remedy implementation than a review of a remedial action under construction. In general, you should assess the following:

- ***Remedial action performance*** – Determine whether the remedial action continues to operate and function as designed (*e.g.*, extent of groundwater plume is well defined and updated plume maps confirm containment), and has achieved, or is expected to achieve, cleanup levels.

- ***System operations/operation and maintenance (O&M)*** – Determine whether maintenance procedures, as implemented, will maintain the effectiveness of response actions. This evaluation might include, but is not limited to, visual inspection of the system and the review and evaluation of monitoring reports (*e.g.*, groundwater data from extraction and monitoring wells, biological monitoring data, discharge requirements, wetland monitoring data, leachate monitoring for containment remedies).

- ***Costs of system operations/O&M*** – Review and consider system operations/O&M costs if they are available. Compare actual/current annual O&M costs to the original cost estimate; large variances from the original cost estimate might indicate potential remedy problems. (Note: This information may not be readily available at Enforcement-lead sites, but should be requested.)

- ***Implementation of institutional controls and other measures*** – Determine whether access controls (*e.g.*, fencing, security guards) and ICs that are needed at this stage of the remediation are in place and successfully prevent exposure. If

ICs are not in place, determine why not, and obtain the schedule for implementation; determine whether other actions (*e.g.*, removals) necessary to ensure that exposure pathways that could result in unacceptable risks have been implemented.

- ***Monitoring activities*** – Determine whether monitoring activities required to ensure the effectiveness of the remedy (*e.g.*, performance and environmental data collected and results evaluated) are being conducted and whether they are adequate to determine the protectiveness and effectiveness of the remedy.

- ***Opportunities for optimization*** – If readily apparent during the course of conducting five-year review activities, identify any opportunities to improve the performance and/or reduce the costs of sampling and monitoring activities and operating treatment systems. If changes in these activities are recommended in the Five-Year Review report, you should also provide the rationale/basis for such changes. If appropriate, your report can also recommend that an optimization study be conducted.

- ***Early indicators of potential remedy problems*** – Investigate and identify problems that could lead to the remedy being not protective or suggest protectiveness is at risk unless changes are made. Problems could include frequent equipment breakdowns or replacement, or large variances in operating costs (if cost data are available). Some examples of indicators of potential remedy problems could include erosion and/or subsidence of a cap, trend analysis of sampling data showing no decrease in contaminant levels, monitoring data showing evidence of leachate migration, or that the extent of the groundwater contamination plume exceeds the outer reaches of the monitoring network.

4.2 Question B: Are the exposure assumptions, toxicity data, cleanup levels, and remedial action objectives used at the time of remedy selection still valid?

In conducting your five-year review, you should evaluate the effects of significant changes in standards and assumptions that were used at the time of remedy selection. Changes in the promulgated standards or "to be considereds" (TBCs) may impact the protectiveness of the remedy. Similarly, you should investigate the effect of significant changes in the risk parameters that were used to support the remedy selection, such as reference doses, cancer potency factors[12], and exposure pathways of concern. Finally, you should evaluate whether the original assumptions regarding current and future land/groundwater uses and contaminants of concern are

[12] Note that risk parameters in EPA publications such as the Integrated Risk Information System (IRIS) (see http://www.epa.gov/IRIS) are guidance only, and should be applied only as appropriate for the remedy being reviewed.

still valid, and whether any physical features (or understanding of physical sites conditions) have changed (*e.g.*, changes in anticipated direction or rate of groundwater or identification of a new groundwater divide). All of these factors may have a bearing on the validity of the remedial action objectives and may affect the protectiveness of the remedy.

Exhibit 4-2 presents a series of example questions that you should consider in determining whether the exposure assumptions and toxicity data used at the time of remedy selection are still valid and, if you determine that they are no longer valid, whether they call into question the protectiveness of the remedy. Exhibit 4-2 also groups the questions according to the type of assumption.

Exhibit 4-2: Example Questions to Determine if Assumptions Upon Which the Remedy was Based Have Changed

For an assumption based on ...	**an example question may be...**
standards and TBCs	Are there changes in the standards identified as ARARs in the ROD that bear on the protectiveness of the remedy? Are there newly promulgated standards that might apply or be relevant and appropriate to the site and that bear on the protectiveness of the remedy? Are there changes in TBCs identified in the ROD that bear on the protectiveness of the remedy?
cleanup levels	What is the basis for each cleanup level identified in the ROD (*e.g.*, risk-based or promulgated standards as ARARs)? Have there been changes to the basis of the cleanup levels? (See sample questions for "standards or TBCs" above, and for "toxicity and other contaminants characteristics" below.)
exposure pathways	Has land use or expected land use on or near the site changed (*e.g.*, industrial to residential, commercial to residential)?
exposure pathways	Have any human health or ecological routes of exposure or receptors changed or been newly identified (*e.g.*, dermal contact where none previously existed, new populations or species identified on site or near the site)?
exposure pathways	Are there newly identified contaminants or contaminant sources?
exposure pathways	Are there unanticipated toxic byproducts of the remedy not previously addressed by the decision documents (*e.g.*, byproducts not evaluated at the time of remedy selection)?
exposure pathways	Have physical site conditions changed such that protectiveness may be affected (*e.g.*, changes in anticipated direction or rate of groundwater flow)? Has understanding of physical site conditions changed (*e.g.*, identification of a new groundwater divide)?
toxicity and other contaminant characteristics	Have toxicity factors for contaminants of concern at the site changed (*e.g.*, Integrated Risk Information System (IRIS) evaluations? (See http://www.epa.gov/IRIS) Have other contaminant characteristics changed? Have ecological toxicity reference values and/or ecological "no observed adverse effect levels/lowest observed adverse effect" (NOAELs/LOAELs) levels changed.

4.2.1 How should I check the impact of changes in standards and TBCs?

Cleanup levels or actions may be based on ARARs identified in the Record of Decision (ROD) (as opposed to calculated site-specific risk, as discussed in Section 4.2.3). For example, the cleanup levels for a groundwater remedy may be based on the Safe Drinking Water Act maximum contaminant levels (MCLs) if these were identified as ARARs in the ROD.

In the preamble to the final National Contingency Plan (NCP), EPA states its policy that it will not reopen remedy selection decisions contained in RODs (*i.e.*, ARARs are normally frozen at the time of ROD signature) unless a "new or modified requirement calls into question the protectiveness of the selected remedy." 55 FR 8757 (March 8, 1990). The preamble goes on to state that "a policy of freezing ARARs at the time of ROD signing will not sacrifice protection of human health and the environment because the remedy will be reviewed for protectiveness every five years, considering new or modified requirements at that point, or more frequently, if there is reason to believe that the remedy is no longer protective of health and environment." 55 FR 8758 (March 8, 1990). The preamble also states that a remedy would not necessarily need to "be modified solely to attain a newly promulgated or modified requirement," but that "newly promulgated or modified requirements contribute to [the] evaluation of protectiveness." 55 FR 8758 (March 8, 1990).

Therefore, although ARARs generally are "frozen" at the time of ROD signature, in conducting a five-year review, you should determine the effect of a newly promulgated or modified standard on the protectiveness of the remedy originally selected in the ROD. You should evaluate the newly promulgated or modified requirement to determine if the cleanup level established in the ROD remains protective. TBCs may also have been used to select cleanup levels. Therefore, you should also review any new or modified TBCs to ensure that any changes will not impact the protectiveness of the remedy.

Generally, you should only consider changes in standards that were identified as ARARs in the ROD, newly promulgated standards for chemicals of potential concern, and TBCs identified in the ROD that bear on the protectiveness of the remedy. As such, you should review any newly promulgated standards, including revised chemical-specific requirements (such as MCLs, ambient water quality criteria), revised action and location-specific requirements, and State standards if they were considered ARARs in the ROD.

In evaluating a change in a standard that was identified as an ARAR in the ROD, or a newly promulgated standard or TBC, you should establish whether the new requirement indicates that the remedy is no longer protective. You should recommend a follow-up action when the remedy is not protective. For example, based on revised risk information for a specific chemical, a new standard (*e.g.*, more stringent MCL for a chemical) may result in a situation where the cleanup level to be achieved by the original remedy would pose a 10^{-3} cancer risk. In that circumstance, the five-year review could recommend that a new cleanup level based on the new

standard be adopted and, if necessary, that the remedy be modified. However, a change in a standard may not necessarily result in a change in the resulting risk and therefore may not always impact protectiveness. An illustration of a method and an example for evaluating changes in standards is provided in Appendix G, "Methods and Examples for Evaluating Changes in Standards and Toxicity," Exhibit G-1, "Evaluating Changes in Standards," Exhibit G-2, "Hypothetical Scenario for a Change in a Standard," and Exhibit G-3, "Decision Process for a Hypothetical Change in Standard."

4.2.2 How should I check the impact of changes in exposure pathways?

You should consider changes in site conditions that could result in increased exposure. These changes could include changed or new land uses, including zoning changes, changed or new routes of exposure or receptors, changed physical site conditions that may affect the protectiveness of the remedy, new contaminants, or a new understanding of geological conditions. In evaluating this information, you should work closely with a risk assessor to establish the impact that such changes may have on the estimated risk associated with your site. Depending on the significance of the changes, it may be necessary for you to recalculate human health risk and re-examine ecological risks. Generally, your human health determination should be based on whether the cancer risk could now be greater than 10^{-4} and/or the hazard index could be greater than 1 for non-carcinogenic effects.

In some cases, it may be necessary to revise or expand the previous risk assessment as part of your five-year review. For example, you may need to revise the risk assessment when there is a new exposure pathway, a new potential contaminant of concern, or an unanticipated toxic byproduct of the remedy. In all cases, you should evaluate whether the remedy can mitigate any unacceptable risk or whether additional actions may need to be taken. Your five-year review can also recommend further investigation to determine whether an additional response action is needed.

4.2.3 How should I check the impact of changes in toxicity and other contaminant characteristics?

Cleanup levels at a site may be based on the calculated risk for chemicals and/or media where there are no promulgated standards (*e.g.*, site-specific soil and sediment action levels) or existing standards are not sufficiently protective for site-specific conditions. If the remedy is intended to meet a site-specific, risk-based cleanup level, you should check to see whether toxicity or other contaminant characteristics used to determine the original cleanup level have changed. In addition to toxicity, you should examine other contaminant characteristics that determine the nature and extent of contaminant migration and effects on receptors (*e.g.* sorption characteristics, ability to bioaccumulate, bioavailability). If there have been changes in the understanding or in our knowledge of these physical/chemical characteristics, you may need to recalculate risk using the original cleanup level or using the current concentration if it has not been identified as a contaminant of concern. An increase in the cancer slope factor, for example,

may suggest that the risk from a chemical concentration is above the generally acceptable cancer risk range (10^{-4} to 10^{-6}). You should also consider changes in toxicity and other contaminant characteristics relating to ecological receptors.

You may work with your Region's risk assessor to determine whether there have been changes in toxicity or other contaminant characteristics and whether further investigation is needed. The risk assessor is also familiar with efficient use of the Superfund Technical Support Center and its hotline. One preferred resource for checking changes in toxicity information is EPA's Integrated Risk Information System (IRIS) (http://www.epa.gov/IRIS). However, many contaminants found at Superfund sites are not found in IRIS. You may find it useful to refer to the Superfund Risk Assessment Tools of the Trade page for databases and additional links and pointers (http://www.epa.gov/superfund/programs/risk/tooltrad.htm#gp). Beginning in the summer of 2001, this page should link risk-based concentration tables which provide screening levels for specific exposure scenarios, a risk calculation tool, and should identify recent toxicity data and their sources.

The flowchart presented in Appendix G, Exhibit G-4, "Evaluating Changes in Toxicity and Other Contaminant Characteristics," shows the process you should use to evaluate the significance of changes in toxicity values and other contaminant characteristics when conducting a five-year review. You should first identify any site-specific, risk-based, cleanup levels and investigate relevant changes in contaminant characteristics. If the estimated risk for a contaminant has not changed, your analysis on this point should be complete.

If the estimated risk has increased, then you should determine whether the new estimated risk is acceptable. In most cases, you should base this determination on whether the risk is within or below the generally acceptable risk range of 10^{-4} to 10^{-6} for carcinogenic risk and the hazard index is below 1 for non-carcinogenic effects. If the estimated risk is not protective, you should determine what actions need to be taken to achieve an acceptable level of risk. Appendix G, Exhibit G-5, "Hypothetical Scenario for a Change in Toxicity," and Exhibit G-6, "Decision Process for a Hypothetical Change in Toxicity," provide an example of the evaluation process when there are changes in toxicity and other characteristics. Note: Future guidance will address the appropriateness of using various statistical methods in making the determination about when remedial action objectives (RAOs) have been attained.

4.2.4 How should I review RAOs and evaluate their impact?

As part of the five-year review, you should conduct an evaluation of the RAOs stated in the ROD to determine whether the remedy is meeting or will meet RAOs. Depending on the outcome of the evaluation, you may find it necessary to modify the RAOs, modify the remedy, or conduct further response actions. For example, an RAO phrased in terms of "achieving the drinking water standard in ten years" may be significantly affected by a new MCL that establishes a more stringent standard. Conversely, an RAO may be general enough to accommodate a new or modified requirement.

If your evaluation of data indicates that the remedy is not meeting and will not be able to meet the RAO stated in the ROD, then you may need to determine if the remedy is protective and, if not protective, what additional actions are needed. For example, if the risk associated with the cleanup levels currently being achieved by the remedy are within EPA's acceptable risk range, the remedy generally should be considered protective. However, if the remedy will not be able to meet the RAOs, further actions may be needed, depending on the specificity of the original RAOs in the ROD. Your Five-Year Review report should identify such further actions as recommendations and/or follow-up actions.

New site conditions, such as discovery of new contaminants, can also impact the RAOs and remedy protectiveness. During your five-year review, you should evaluate whether the RAOs in the ROD are sufficiently comprehensive to cover any new or changed conditions at a site. If a new condition at the site is not covered by the RAOs, you should recommend further investigation in the Five-Year Review report to determine whether additional response actions are needed.

Further response actions may not necessarily involve additional physical construction activities but could include sampling, studies, and/or investigations. For example, modifying RAOs will require a ROD Amendment, but does not require a physical site activity.

4.3 Question C: Has any other information come to light that could call into question the protectiveness of the remedy?

You should consider any other information that comes to light that could call into question the protectiveness of the remedy. It is expected that most considerations related to the protectiveness of the remedy will be covered by Questions A and B. However, in some instances, there may be other factors about the remedy or the site that you should consider during the review.

Situations to watch for include the following:

- Ecological risks have not been adequately addressed at a site, and there is not a plan to address them through a future action;
- The site, although located entirely above the 500-year flood boundary, was partially inundated by a 100-year flood (which now may require a flood plain redesignation of the region); and
- Land use changes that are being considered by local officials.

If ecological risks have not been adequately addressed at a site, and there is not a plan to address them through a future action, then you may need to address them by conducting a screening ecological risk assessment as part of the Five-Year Review using *Final Guidance: Ecological Risk Assessment and Risk Management Principles for Superfund Sites*, OSWER

Directive 9285.7-28P (October 7, 1999). The ecological risk assessor on your team can help streamline the process appropriately.

4.4 How should I develop the conclusions of my five-year review?

The conclusions of your five-year review should include: 1) an identification of issues; 2) recommendations and follow-up actions; and 3) a determination of whether the remedy is, or is expected to be, protective of human health and the environment. You should arrive at these conclusions through a technical assessment of the information collected during the document review, data collection, interviews, site inspection, and other activities. Your evaluation should focus on the information collected through answering the three questions shown in Exhibit 4-1. (See Sections 4.1, 4.2, and 4.3, above, for a detailed discussion of how to assess the remedy by answering these three questions.) These conclusions should be documented in the Five-Year Review report as a technical assessment summary.

4.4.1 How should I identify issues?

You should identify all issues that currently prevent the response action from being protective, or may do so in the future. You should document all such issues and follow-up actions needed to ensure the proper management of the remedy in your Five-Year Review report. You should also identify early indicators of potential remedy problems. Early indicators of remedy problems may include operating costs that are greater than originally anticipated. For instance, excessive replacement of pumps or other equipment may indicate the need to reconsider system design or re-evaluate aquifer conditions.

Examples of issues that may be identified in a Five-Year Review report include the following:

- Inadequate access controls (*e.g.*, fencing has been breached, or fencing is not adequate to restrict access);
- Incomplete response action, including ICs (*e.g.*, environmental easements or well restrictions are not in place);
- Inadequate ICs (*e.g.*, well restrictions are in place but are not preventing exposure);
- Response action is not expected to achieve cleanup levels; plume containment has not been confirmed or achieved;
- Cleanup levels are not protective due to changes in chemical characteristics;
- Discharge requirements are exceeded;
- Inadequate operation and maintenance of physical remedial structures (*e.g.*, vegetative cover of cap mowed infrequently);

- Differences found in actual or proposed land use other than those assumed in the selection of the response action;
- RAOs will not be achieved;
- Monitoring is not being completed in a timely manner; and
- Inadequate monitoring activities to determine the protectiveness of the remedy (*e.g.*, the number and location of monitoring wells are not appropriate for monitoring remediation progress of the groundwater contamination plume).

You should describe each issue in sufficient detail so that EPA can appropriately track the progress to resolution. For each issue, you should determine if it currently affects the protectiveness of the remedy or may do so in the future.

Exhibit 4-3 provides an example of a tabular format that you can use to list issues in your Five-Year Review report.

Exhibit 4-3: Example Table for Listing Issues

Issues	Affects Protectiveness (Y/N)	
	Current	Future

4.4.2 When and how should I develop recommendations?

For each issue identified, the Region should document and ensure implementation of recommendations to resolve those issues. These recommendations should be identified along with follow-up actions in your Five-Year Review report. Follow-up actions should be completed to ensure long-term protectiveness of the remedy, or to bring about protectiveness of a remedy that is currently not protective. You may also have follow-up actions where a protectiveness determination cannot be made at the time of the five-year review. In addition, you may wish to make additional recommendations that do not directly relate to achieving or maintaining the protectiveness of the remedy, such as activities related to O&M of the remedy and coordination with other public and government authorities.

The following are types of recommendations that generally are considered appropriate as part of a five-year review:

- ***Provide additional response actions*** – For example, additional response actions may be necessary to ensure protectiveness if new risk information indicates that a remedy is not protective (*e.g.*, a treatment process will not be able to achieve soil cleanup levels). EPA may implement such further response any time pursuant to CERCLA §104 or §106 authority. In your Five-Year Review report, you can recommend further investigation and the implementation of further response actions.

- ***Improve O&M activities*** – For example, when a cap's vegetative cover is not mowed on a regular basis and/or vegetation other than that specified in the remedial construction contract specifications is present, you may recommend that actions be taken to improve compliance with the O&M Manual/Plan. The lack of O&M activities can lead to more serious remedy problems if not addressed. Your Five-Year Review report should recommend that O&M activities be conducted if they currently are not being performed or inadequately conducted and, if needed, expanded, reduced, or terminated. The report should also provide the rationale/basis for any of these recommendations.

- ***Optimize remedy*** – For example, when the limits of a groundwater plume have contracted due to pumping, and some monitoring wells no longer register contamination levels above cleanup levels, it may be appropriate to revise the sampling plan to eliminate these wells from the sampling routine or reduce the frequency of their sampling. It may also be possible to remove specific groundwater extraction wells from service and increase or reduce the pumping rate on others to optimize groundwater remediation. Similarly, it may be possible to remove treatment units that no longer contribute to the achievement of remedial goals.

- ***Enforce access controls and ICs*** – For example, when repeated site trespassing has been observed, you could recommend repair of the fence and an evaluation of the need for additional security measures. When you have evidence that groundwater wells continue to be installed despite well restrictions that are currently in place, you can recommend an evaluation of the need for further enforcement of institutional controls (*e.g.*, prohibit well drilling).

- ***Conduct additional studies or investigations*** – For example, after reviewing and evaluating all available data and information it is apparent that contaminant levels have not decreased as expected in the estimated time frame. Additional information will be needed to determine if the remedy, as is, will be able to achieve remediation goals within the estimated time frame. Other studies may include, but are not limited to, site characterization, ecological assessment,

focused feasibility studies, groundwater modeling, treatability studies, and/or sampling.

For each recommendation, you should identify the party responsible for implementation, the agency with oversight authority, a recommended schedule for implementation and completion, and the impact, if any, on current or future protectiveness. Exhibit 4-4 provides an example of a table that you can use in your Five-Year Review report for documenting both recommendations and follow-up actions.

Exhibit 4-4: Example Table for Listing Recommendations and Follow-up Actions

Recommendations/ Follow-up Actions	Party Responsible	Oversight Agency	Milestone Date	Follow-up Actions: Affects Protectiveness (Y/N)	
				Current	Future

Regions should track the progress and completion of recommendations and/or followup actions with documentation in the site file, and upon completion update the administrative record in the site information repository. See Section 3.8 for annual reporting responsibilities to EPA Headquarters.

4.5 How do I determine protectiveness?

After addressing Questions A, B, and C, you should be ready to determine the protectiveness of the remedy or remedies at a site and to document the rationale for your determination(s). You should make a protectiveness statement for each OU and an additional, comprehensive site-wide protectiveness statement for those sites that have reached construction completion.

Your determination of whether the remedy remains protective of human health and the environment generally should be based on the answers to Questions A, B, and C and the information obtained in the process of answering them. Although protectiveness generally is defined by the risk range and hazard index (HI), your answers to Questions A, B, and C may identify other factors and issues that may impact the protectiveness of a remedy.

At the end of your technical analysis and evaluation, if the answers to Questions A, B, and C are *yes, yes, and no*, respectively, then your remedy normally should be considered

protective. However, if the answers to the three questions are other than *yes, yes, no,* depending on the elements that affect each question, your remedy may be one of the following:

- Protective;
- Will be protective once the remedy is completed;
- Protective in the short-term; however, in order for the remedy to be protective in the long-term, follow-up actions need to be taken;
- Not protective, unless the following action(s) are taken in order to ensure protectiveness; or
- Protectiveness cannot be determined until further information is obtained. (A time frame should be provided when a protectiveness determination will be made. This should be done through an addendum. If this is the case, your next five-year review should be due five years from the date this report is signed, not the signature date of the addendum).

Even if there is a need to conduct further actions, it does not mean that the remedy is not protective. Normally, the remedy should be considered as not protective when the following occur:

- An immediate threat is present (*e.g.* exposure pathways that could result in unacceptable risks are not being controlled);
- Migration of contaminants is uncontrolled and poses an unacceptable risk to human health or the environment;
- Potential or actual exposure is clearly present or there is evidence of exposure (*e.g.*, institutional controls are not in place or not enforced and exposure is occurring); or
- The remedy cannot meet a new cleanup level and the previous cleanup level is outside of the risk range.

Exhibit 4-5 presents examples of protectiveness determinations. These examples cover only some of the possible situations you may observe at your site but should serve to guide your decision-making.

Exhibit 4-5: Examples of Protectiveness Determinations

1. Remedies Under Construction			
If the remedy involves...	**and you observe in your five-year review that...**	**then your answers to Questions A, B and C should be...**	**and...**
any remedial action under construction	• no changes to site conditions or any other parameters would impact protectiveness	A - Yes B - Yes C - No	the remedy will be protective.
a groundwater pump-and-treat system expected to operate for 30 years with institutional controls to restrict well drilling of groundwater wells	• an MCL for one of the contaminants of concern (COCs) has become more stringent since the ROD was signed; and the risk associated with the previous MCL is now outside of the risk range; • the remedy cannot meet the new standard (even with design modifications); and • ICs are in place,	A - Yes B - No C - No	the remedy is not protective because the remedy is not able to meet the new standard (ARAR) and the previous MCL is outside of the risk range. However, since ICs are in place there are no current exposures. Recommend that follow-up actions be taken to address the new MCL (ARAR) issue.
rerouting of contaminated surface runoff from tailings	• remedy in the ROD did not address ecological risks; • sediment sampling data from adjacent wetlands indicate high levels of heavy metals; • there were dead fish, and land animals with physical abnormalities; or • an ecological risk assessment was not previously conducted,	A - Yes B - Yes C - Yes	defer protectiveness because more information is needed to make a protectiveness determination. Recommend that follow-up actions be taken to address inadequate ecological risk data.

Question A – Is the remedy functioning as intended by the decision documents?
Question B – Are the exposure assumptions, toxicity data, cleanup levels, and remedial action objectives (RAOs) used at the time of the remedy selection still valid?
Question C – Has any other information come to light that could call into question the protectiveness of the remedy?

Exhibit 4-5: Examples of Protectiveness Determinations

2. Operating Remedies			
If the remedy involves...	**and you observe in your five-year review that...**	**then your answers to questions A, B and C should be...**	**and...**
any operating remedy	• no changes to site conditions or any parameters under Questions A, B, and C occurred,	A - Yes B - Yes C - No	the remedy is protective.
groundwater pump-and-treat system expected to operate for 15 years with ICs to restrict well drilling	• no well drilling restriction in place as required by ROD; • there is no known current exposure to groundwater, based on site visits, interviews with local officials and residents,	A - No B - Yes C - No	the remedy is considered protective in the short-term, because there is no evidence that there is current exposure. However, in order for the remedy to remain protective in the long-term, ICs restricting well drilling must be put in place.
groundwater pump-and-treat for 20 years; ICs restricting well drilling; RAO: restore groundwater to drinking water standards	• based on data and current groundwater modeling, the RAOs will not be met; • ICs are in place; • the system has been operating for ten years; • there are no changes in standards or contaminant characteristics for COCs; • there are no new standards; • contaminant levels of COCs have leveled off in the last five years; • optimization efforts have not been effective in further decreasing COC levels; • current levels of contamination are within EPA's risk range, however, RAOs have not yet been achieved,	A - No B - No C - No	the remedy is considered protective in the short-term because ICs are in place, and therefore, there is no current or potential exposure. Follow-up actions are necessary to address long-term protectiveness because RAOs are not expected to be met. Recommend that the remedial action objectives may need to be reevaluated and other potential actions be further evaluated.

Question A – Is the remedy functioning as intended by the decision documents?
Question B – Are the exposure assumptions, toxicity data, cleanup levels, and remedial action objectives (RAOs) used at the time of the remedy selection still valid?
Question C – Has any other information come to light that could call into question the protectiveness of the remedy?

Exhibit 4-5: Examples of Protectiveness Determinations

If the remedy involves...	**and you observe in your five-year review that...**	**then your answers to questions A, B and C should be...**	**and...**
groundwater pump-and-treat for 10 years; ICs on well drilling; RAO: groundwater restoration to beneficial use	• ICs are in place; • there is a new State MCL for one of the COCs; • the standard (ARAR) in the original ROD is still protective because it is within the same order of magnitude as the new State MCL and remains within EPA's risk range; • there is no current exposure - residents with private wells in the area are on alternate water supply; • the State considers all groundwater to be a potential source of drinking water (However, there is no Comprehensive State Groundwater Protection Plan [CSGWPP]); and • the existing remedy (system) can achieve the new MCL,	A - Yes B - No C - No	the remedy is considered protective because the cleanup levels are still within EPA's risk range and there is no current or potential exposure.

Question A – Is the remedy functioning as intended by the decision documents?
Question B – Are the exposure assumptions, toxicity data, cleanup levels, and remedial action objectives (RAOs) used at the time of the remedy selection still valid?
Question C – Has any other information come to light that could call into question the protectiveness of the remedy?

Exhibit 4-5: Examples of Protectiveness Determinations

If the remedy involves...	and you observe in your five-year review that...	then your answers to questions A, B and C should be...	and...
groundwater pump-and-treat for 20 years; ICs restricting well drilling; RAO: groundwater restoration to drinking water standards	• ICs are in place; • new Federal standard for one of the COCs; • the standard (ARAR) in the original ROD is still protective, within EPA's risk range; • no current or potential exposure to groundwater; and • existing remedy can remediate groundwater to the new standard,	A - Yes B - No C - No	the remedy is considered protective because cleanup levels are still within the risk range and there is no current or potential exposure. However, if the new MCL is not met, the groundwater will not meet the RAO of restoration to drinking water standards. Recommend consideration of follow-up actions to address the new standard and the issue of not achieving the RAO. However, in this case, the remedy can meet the new standard, and therefore, another option is to recommend that the new standard be adopted as the new cleanup level, which would then allow you to achieve the original RAOs. Adopting a new cleanup level would have to be done through the remedy decision process with a ROD Amendment or Explanation of Significant Differences (ESD).

Question A – Is the remedy functioning as intended by the decision documents?
Question B – Are the exposure assumptions, toxicity data, cleanup levels, and remedial action objectives (RAOs) used at the time of the remedy selection still valid?
Question C – Has any other information come to light that could call into question the protectiveness of the remedy?

Exhibit 4-5: Examples of Protectiveness Determinations

3. Completed Remedies			
If the remedy involves...	**and you observe in your five-year review that...**	**then your answers to questions A, B and C should be...**	**and...**
any remedy that is complete with a five-year review requirement	• there were no changes to site conditions or parameters under questions A, B, and C,	A - Yes B - Yes C - No	the remedy is protective.
capping of 30-acre landfill with ICs to prevent disturbance of cap	• ICs were never put in place; • mowing and cap maintenance activities are ongoing and adequate; • there is no cracking, sliding, settlement of cap or other indicators of cap breaches; and • there is no evidence of an exposure (human or ecological),	A - No B - Yes C - No	the remedy is considered protective in the short-term because there is no evidence of a cap breach and thus no current exposure. However, in order for the remedy to remain protective in the long-term, ICs must be put in place.
groundwater pump-and-treat for 10 years; ICs restricting well drilling; RAO: restore groundwater to drinking water standards; cleanup goals were achieved and RAOs were met (third five-year review is being conducted as a matter of policy in order to facilitate the deletion process)	• there is a new standard for one of the COCs; • Standard in original ROD (ARAR) is now outside of the risk range (due to a change in toxicity); and • ICs are no longer in place because RAOs were met last year,	A - Yes B - No C - No	the remedy is not protective because the standard in the ROD is no longer within the risk range and therefore no longer protective. In addition, the RAO is no longer being met. Recommend follow-up actions necessary to make remedy protective and deletion should not occur until this issue is resolved.

Question A – Is the remedy functioning as intended by the decision documents?
Question B – Are the exposure assumptions, toxicity data, cleanup levels, and remedial action objectives (RAOs) used at the time of the remedy selection still valid?
Question C – Has any other information come to light that could call into question the protectiveness of the remedy?

Exhibit 4-5: Examples of Protectiveness Determinations

If the remedy involves...	and you observe in your five-year review that...	then your answers to questions A, B and C should be...	and...
excavation and disposal of top two feet of contaminated soil; ICs prohibiting residential and recreational use of the property; RAO: cleanup site to allow for industrial use; site was deleted three years ago	• ICs are still in place; • the remedy is intact, no physical disturbances, top two feet of clean soil remain undisturbed; and • the local government is considering changing the zoning of the property to allow for recreational use,	A - Yes B - Yes C - No	the remedy is considered to be currently protective. However, should the zoning of the property change to recreational use, the remedy may no longer be protective. Recommend follow-up actions with local officials to ensure that in the event that zoning changes the remedy will remain protective.

Question A – Is the remedy functioning as intended by the decision documents?
Question B – Are the exposure assumptions, toxicity data, cleanup levels, and remedial action objectives (RAOs) used at the time of the remedy selection still valid?
Question C – Has any other information come to light that could call into question the protectiveness of the remedy?

4.5.1 How do I formulate protectiveness statements?

You should develop a protectiveness statement for each OU at which a remedial action has been initiated. For sites that have reached construction completion and have more than one OU, you should develop an additional comprehensive site-wide protectiveness statement covering all of the remedies at the site. You should not include this additional protectiveness statement until construction completion because, until then, all remedies at the site may not necessarily have been selected and constructed.

In order to promote consistency, you are strongly encouraged to model your protectiveness statements on the sample protectiveness statements provided in Exhibits 4-6 and 4-7. Your Five-Year Review report should present the protectiveness statements at the beginning of a discussion that should explain and provide the supporting rationale of the protectiveness determination.

Exhibit 4-6: Protectiveness Statements

If the remedial action at the OU is:	then use this statement ...
under construction and...	
protective or will be protective	"The remedy at OU X is expected to be protective of human health and the environment upon completion, and in the interim, exposure pathways that could result in unacceptable risks are being controlled."
not protective	"The remedy at OU X is not protective because of the following issue(s) (describe each issue). The following actions need to be taken (describe the actions needed) to ensure protectiveness."
protectiveness deferred	" A protectiveness determination of the remedy at OU X cannot be made at this time until further information is obtained. Further information will be obtained by taking the following actions (describe the actions). It is expected that these actions will take approximately (insert time frame) to complete, at which time a protectiveness determination will be made."

Exhibit 4-6: Protectiveness Statements

If the remedial action at the OU is:	**then use this statement ...**
operating or completed and...	
protective	"The remedy at OU X is expected to be protective upon completion or is protective of human health and the environment, and in the interim, exposure pathways that could result in unacceptable risks are being controlled."
protective in the short-term	"The remedy at OU X currently protects human health and the environment because (describe the elements of the remedy that protect human health and the environment in the short term). However, in order for the remedy to be protective in the long-term, the following actions need to be taken (describe the actions needed) to ensure long-term protectiveness."
not protective	"The remedy at OU X is not protective because of the following issue(s) (describe each issue). The following actions need to be taken (describe the actions needed) to ensure protectiveness.
protectiveness deferred	" A protectiveness determination of the remedy at OU X cannot be made at this time until further information is obtained. Further information will be obtained by taking the following actions (describe the actions). It is expected that these actions will take approximately (insert time frame) to complete, at which time a protectiveness determination will be made."

Exhibit 4-7: Comprehensive Protectiveness Statements for Sites That Have Reached Construction Completion

If the remedy(ies) is/are ...	**then use this statement:**
protective	"Because the remedial actions at all OUs are protective, the site is protective of human health and the environment."
not protective	"The remedial actions at OUs X and Y are protective. However, because the remedial action at OU Z is not protective, the site is not protective of human health and the environment at this time. The remedial action at OU Z is not protective because of the following issue(s) (describe each issue). The following actions need to be taken (describe the actions needed) to ensure protectiveness."

Appendix A
Community Involvement

[This page intentionally left blank.]

Community Involvement

This appendix provides a brief discussion about community involvement during the five-year review with a focus on the role of the 40 CFR §300 Community Involvement Coordinator (CIC), community involvement activities, notifying the community, additional recommended activities at high visibility sites, elements of a communications strategy, interviewing members of the community, an example timeline of communication activities, and sources for additional information on community involvement.

What is the role of the Community Involvement Coordinator (CIC)?

The Community Involvement Coordinator (CIC) serves as a public participation and communications advisor. It is his/her job to ensure effective communications with the community. You should consult with the CIC about the most appropriate methods for notifying and involving the community in the five-year review process. The CIC may advise, develop and implement activities designed to notify the community and to involve the community. Part of the community involvement process should involve reviewing the existing Community Involvement Plan (CIP) for the site. The CIP typically describes the history of the site, including any community involvement activities conducted in the past or special needs of the community. Many changes may have taken place in the community since the CIP was last revised or since the last five-year review. For example, the demographics of the community may have changed and new businesses and residents may live in the area. Some residents may speak a language other than English. The CIC can arrange for an interpreter and written materials can be translated into the appropriate language.

When should I begin community involvement activities?

You should begin working with the site's Regional CIC during the initial planning stages of the five-year review to determine the appropriate level of community involvement for the five-year review.

What points should be covered in notifying the community?

At a minimum, community involvement activities during the five-year review should include notifying the community that the five-year review will be conducted and notifying the community when the five-year review is completed. The CIC can recommend appropriate communication vehicles for notifying the public (*e.g.*, publishing a public notice in the newspaper, radio announcement, etc).

The site team should determine the best means for notifying the community that the five-year review process is underway. In some communities, holding an open house or public meeting where community members may stop by and ask questions or pick up fact sheets, brochures, etc., may work effectively. Other activities may include broadcasting a public service

announcement on radio or television and mailing, posting, or handing out a fact sheet. Depending on the nature of the site and the interest in the community, another option for involving the public is to provide a public comment period on the findings of the five-year review.

Notice to the community that a five-year review will be conducted should at a minimum provide:

- The site name, its location and web address (if available);
- The lead agency conducting the review;
- A brief description of the selected remedy;
- A summary of contamination addressed by the selected remedy;
- How the community can contribute during the review process;
- A contact point and phone number for further information; and
- The scheduled date of completion of the five-year review.

Notice to the community that a five-year review has been completed should include some of the information given in the initial notice plus additional information. At a minimum, the notice that a five-year review has been completed should include:

- The site name, its location, and web address (if available);
- The lead agency conducting the review;
- A brief description of the selected remedy;
- A summary of contamination addressed by the selected remedy as provided in the initial notice;
- A brief summary of the results of the five-year review;
- The protectiveness statement(s);
- A brief summary of data and information that provided the basis for determining protectiveness, issues, recommendations, and follow-up actions directly related to the protectiveness of the remedy;
- Location(s) where a copy of the five-year review can be obtained or viewed (including site repositories);
- A contact name and telephone number where community members can obtain more information or ask questions about the results; and
- The date of the next five-year review or a statement and supporting rationale that five-year reviews will no longer be required.

Are there any additional recommended activities that I should consider at high visibility sites?

At high profile sites or those with significant public interest, you should carefully consider methods for informing the community about the review. You should determine if additional or enhanced community involvement activities are appropriate. During the five-year review, active community members may be interested in some or all of the following topics:

- The five-year review process;
- How community members or groups can contribute information about site activities;
- Where to find written documentation about the review;
- What the protectiveness statements mean; and
- What happens after the review is complete, especially if the remedy is found to be not protective.

The CIC and other review team members that have knowledge of the community's needs and interests should be involved in decisions about the level of community involvement and appropriate activities.

What elements should I include when developing a communication strategy?

It is always a good idea to develop a communication strategy for high profile sites. This strategy should:

- Describe the public's concerns and communication needs;
- Identify specific communication activities that you plan to conduct;
- Outline a proposed schedule for these activities, and assign responsibilities for carrying them out; and
- Present expected results.

Consult Section V of the *Superfund Community Involvement Handbook (OSWER Directive 9230.0-94) and Toolkit (OSWER Directive 9230.0-95)* for an example of a communication strategy. This strategy does not need to be added to the official record, and can be as informal or detailed as community needs demand.

How should I approach interviewing members of the community?

In addition to notifying the community about the five-year review, you and the CIC, in conjunction with the site team, should consider interviewing community members (especially those living near the site) to get their views about site conditions and related concerns. If there is a Community Advisory Group or a group with a Technical Assistance Grant related to the site, they should be briefed at the outset of the five-year review process in addition to other interviews you may conduct.

You, the CIC, and other team members should review the community profile in the CIP to obtain useful information about the community, such as business owners or residents living near the site, and the past level of interest from individuals and groups in the community. The CIP can also be a source for identifying other stakeholders who have been active in site activities in the past and who could provide additional information about site conditions.

Other important sources of information are local officials. In many cases, the CIC may be the best person to consult local officials, because they may have met or spoken with them previously and established rapport.

See Appendix C, "Five-Year Review Interviews," for additional information about conducting interviews as part of a five-year review.

What is the timeline for communication activities during a five-year review?

Table 1, "Major Communication Milestones During a Five-Year Review," outlines the major communication milestones during a five-year review and a suggested time frame for conducting communication activities, especially at high profile sites or those with a strong public interest. Consult the *Superfund Community Involvement Handbook and Toolkit* to determine which activities may be best suited for your community at each stage, and for details on the time frame and effort needed for each activity. Activities may be conducted before or at the outset of your five-year review and during or close to the time of the site inspection, depending on the community needs. Activities that you should conduct for all five-year reviews are identified in Table 1 with bolded text.

Table 1: Major Communication Milestones During a Five-Year Review

When you or the CIC...		you should...
Planning the Review and Notifying the Community		
1.	review the existing CIP for potentially helpful information (the CIC should lead this effort),	begin planning immediately, so that if interaction with the community is needed, it is provided up-front.
2.	develop a communication strategy,	prepare a communication strategy before notifying the community. Circumstances and the level of public interest may change throughout the process, so refer to and update the strategy regularly.
3.	**notify the community that the five-year review will begin, using a communication activity appropriate to the specific community,**	notify the community that the five-year review process is beginning before the site inspection.
Consulting the Community		
4.	interview community members to gather additional information about the site,	plan for about one month of coordination and gathering of information, depending on whether contact with the community is via telephone, in person, etc.
Communicating the Results of the Five-Year Review		
When you or the CIC...		**you should...**
5.	plan and conduct additional communication activities tailored to community needs at each site,	plan your activities before releasing the results of the five-year review to the public. Try to complete these activities before the release of the report or within six months after the Five-Year Review report is complete.
6.	**notify the community that the Five-Year Review report is complete, prepare and distribute a brief summary of the results, and place the report in the site information repositories,**	provide this information as quickly as possible after the Five-Year Review report is completed. Consult with the CIC before preparing the summary to determine which communication mechanism is most appropriate to the community's needs.

Note: Bolded activities are required

More Information on Community Involvement

For more information on community involvement activities, please consult the following sources:

- ***The Superfund Community Involvement Handbook (OSWER Directive 9230.0-94) and Toolkit (OSWER Directive 9230.0-95).*** This two-volume handbook and toolkit includes guidance on community involvement policy throughout the Superfund pipeline, including special chapters on working at Federal facilities, risk communication, and multimedia sites. The toolkit components describe and provide over 100 tools that CICs can use to make their jobs easier, such as electronic and hard copy templates for public notices, press releases, fact sheets, communication strategies, etc.

- ***The Superfund Community Tools Home Page.*** There are a number of information resources available on the EPA Web Site. Point your Web browser to http://www.epa.gov/superfund/action/community/index.htm to access the Superfund Community Tools Home Page.

Appendix B
Document Review

[This page intentionally left blank.]

Document Review

The following six sections provide examples of potential documents to be reviewed as part of a five-year review. Each section addresses a different aspect of the document review. Documents commonly reviewed are displayed in a table in each section. Every site is different, so it may be necessary to review additional documents, such as relevant Memoranda of Understanding, to fully understand the remedial actions at a site. The tables and text below should be used as a guide.

- Basis for the Response Action;
- Implementation of the Response;
- Operation and Maintenance;
- Remedy Performance;
- Legal Documentation; and
- Community Involvement.

Basis for the Response Action

Remedy decision documents, and Federal and State laws and regulations, provide the basis upon which the remedy was selected or modified. The documents in the table below identify the background and goals of the remedy and any changes in laws and regulations that may affect the remedy. Other sources of remedy decision information are the Remedial Investigation/Feasibility Study (RI/FS) Report, toxicological and chemical characteristics databases, and transcripts of public meetings.

Non-remedial responses have other types of documentation. For instance, removal actions frequently are documented through an Action Memorandum. You should adapt your review of those documents to the circumstances at your site.

Document	Purpose of Document	Use During the Five-Year Review
Decision Documents – RODs – ROD Amendments – Explanations of Significant Differences – Action Memoranda	– records remedial decision or other actions, and significant changes from the original remedy	– goals of the remedy – background information on the site – basis for action – cleanup levels and applicable or relevant and appropriate requirements (ARARs) – community concerns and preferences

Document	Purpose of Document	Use During the Five-Year Review
Federal Environmental Laws and Regulations	– statutory and regulatory requirements that may affect the judgement as to whether the remedy protects human health and the environment	– changes in standards identified as ARARs in the ROD that provide a basis for cleanup levels/protectiveness of the remedy (only ARARs related to protectiveness need be reviewed) – pertinent laws and regulations promulgated since the signing of the ROD that are potentially applicable or relevant and appropriate and that potentially bear on the protectiveness of the remedy
State Environmental Laws and Regulations	– statutory and regulatory requirements that may affect the judgement as to whether the remedy protects human health and the environment	– more stringent State environmental laws and regulations have the same standing under the National Contingency Plan (NCP) as Federal laws and regulations, and should be reviewed in the same manner when they may call into question whether the remedy protects human health and the environment (the State typically should perform this component of the review)

Implementation of the Response

Implementation documents furnish information about design assumptions, design plans or modifications, and documentation of the completion of construction at operable units (OUs) and the site. Design reports, plans, and specifications are other documents that provide further information.

Document	Purpose of Document	Use During the Five-Year Review
Remedial Action Reports (both interim and final)	– documents that for a single operable unit all construction activities are complete, the remedy is operational and functional, and that cleanup levels have been achieved – Interim Remedial Action Reports are used for long-term actions where cleanup levels have not yet been achieved	– detailed history and status of remedial actions
As-built drawings	– documents changes/modifications to the original design which occurred during the construction	– documentation of completed action and/or implemented remedy

Document	Purpose of Document	Use During the Five-Year Review
Close Out Reports (Preliminary and Final)	– the preliminary report documents that all physical construction for all operable units at a site is complete – the final report documents cleanup levels have been met	– background information and the status of the remedial actions at the site

Remedy Performance

Monitoring data, progress reports, and performance evaluation reports provide information that can be used to determine whether the remedial action continues to operate and function as designed (*e.g.*, extent of groundwater plume is well defined and update plume maps confirm containment), and has achieved, or is expected to achieve, cleanup levels. The data presented in these documents can also provide trend analysis which can be used to determine how well the remedy is performing and how long it will take to achieve remediation goals. These reports can also indicate whether monitoring activities are adequate to ensure the effectiveness of the remedy (*e.g.*, wells in locations that can show contaminant plume is contained and not migrating) and whether these activities are being conducted.

Document	Purpose of Document	Use During the Five-Year Review
Monitoring Information/Records/Progress Reports (information could include air sampling, groundwater monitoring data, survey/settlement monument records, and gas generation records data/performance evaluation)	– records monitoring data and other information, including contaminant levels – trend analysis – containment evaluation	– to check whether contaminant levels are within established criteria – whether cleanup levels will be achieved – (for containment remedies) contaminant plumes are being contained

Operation and Maintenance (O&M)

O&M documents describe the ongoing measures at a site to ensure the remedy remains protective. (Long-term response actions to restore groundwater and surface water during the remedial phase are referred to as "system operations" in this guidance. Although this section refers to O&M documents, similar documents should be reviewed to assess system operations.) They provide the structure for O&M at the site and confirm that O&M is proceeding as planned. O&M documents that may be helpful are the O&M Manual, O&M Plan, the O&M Contract, O&M and Occupational Safety and Health Administration (OSHA) Training Records, permits and service agreements, and access and security logs. Other types of O&M data to be reviewed include permit compliance data such as air or water discharge sampling results, facilities operation data such as treatment train operational records, gas monitoring and leachate collection data, maintenance records and logs, and O&M cost data. These data demonstrate the proper O&M of the remedy.

Document	Purpose of Document	Use During the Five-Year Review
O&M Manual	– contains technical information necessary to operate and maintain the remedy	– purpose and function of the equipment and systems which comprise the overall facility
O&M Reports	– documents O&M activities, data, and costs	– to check whether O&M is proceeding as planned
Discharge Permits and Deviations*	– notes contaminant levels for the discharge permits – notes contaminant levels for deviations	– to check whether the remedy is operating within design parameters

* Permits are not required for actions taken on site. Reviewer should focus on ensuring compliance with substantive requirements of otherwise permitted activities.

Legal Documentation

Legal documentation pertinent to the site may specify responsibilities for conducting remedial actions, implementing institutional and access controls, O&M activities, and performing elements of the five-year reviews.

Document	Purpose of Document	Use During the Five-Year Review
Enforcement Documents – Consent Decrees – Unilateral Administrative Orders – Administrative Orders on Consent	– commitments/ agreements regarding implementation and operation of the remedy, and conduct of studies – access agreements that are needed	– responsibilities of the PRP for conducting remedial activities at various stages of site cleanup – O&M requirements (when these documents are used to enforce the performance of O&M, they may incorporate O&M documents, such as the O&M Manual)
Institutional Controls (deed notices, easements, other conditions, covenants or restrictions on deeds, and groundwater and land use restriction documents)	– means to restrict the use of a parcel or an associated resource, such as groundwater	– status of institutional controls
Superfund State Contracts and Cooperative Agreements	– State assurance letters to conduct O&M – State authorities responsible for O&M – specific O&M requirements – agreements with Indian Tribes	– O&M implementation and reporting requirements – roles of different agencies
Interagency Agreements and Federal Facility Agreements	– responsibilities of other agencies	– O&M guidelines and rules in effect (sometimes other agencies adopt their own guidelines and rules, which must be consistent with those established by EPA)

Community Involvement

The Community Involvement Plan (CIP) may give you a better understanding of the history of community involvement, and of other activities at the site. In addition, the CIP may help you identify community members who would be valuable resources during the interview process.

Document	Purpose of Document	Use During the Five-Year Review
Community Involvement Plan	– site communication strategy that specifies outreach activities	– community concerns/issues and identification of appropriate community members for interviews

[This page intentionally left blank.]

Appendix C
Five-Year Review Interviews

[This page intentionally left blank.]

Five-Year Review Interviews

Information gathered from interviews during the site inspection may be key to understanding site status. Interviews should be conducted with various individuals or groups, including the operation and maintenance (O&M) site manager, O&M staff, local regulatory authorities and response agencies, community action groups or associations, site neighbors, and other stakeholders.

When conducting an interview, the interviewer should note the date of the interview, and the name, title, and affiliation of the person interviewed. The interviewer should also indicate whether the interview was conducted at the site, the office, or by phone. Written documentation of the interview should briefly summarize the discussion, address any problems or successes with the implementation of the remedy, and provide suggestions for future reference. Forms to use during interviews are provided at the end of this appendix.

The following tables provide lists of potential individuals to interview and the type of information which may be obtained during the interviews. The potential individuals to be interviewed are categorized by their ability to provide the following types of information:

- Background information;
- State and local considerations;
- Construction considerations; and
- Performance, Operation and maintenance problems.

All of these individuals may be contacted during the five-year review. In most cases interviewing only a few key individuals will provide sufficient information for the review.

Background Information

The individuals listed below may provide information concerning previous and current concerns about the site, influences that affected the remedy decision, and further clarification on decisions made during remedy selection.

Interview	Information Sought
Previous EPA Staff/Management	– staff members may offer insight and clarification on decisions made during remedy selection and implementation
Nearest Neighbors	– neighbors may provide insight into the enforcement of institutional controls, changes in land use, trespassing, and unusual or unexpected activity at the site

Interview	Information Sought
Community Representatives*	– members of the community may provide a broader view of site activities and issues than can be obtained during the site inspection

* Several types of individuals may be interviewed: residents/businesses adjacent to or on the site; residents/businesses within the path of migration; local civic leaders, local officials, Community Advisory Group (CAG), Technical Assistance Grant (TAG) group, and local environmental groups; and other audiences listed in the community profile in the Community Involvement Plan.

Some example interview questions are given below.

1. What is your overall impression of the project? (general sentiment)

2. What effects have site operations had on the surrounding community?

3. Are you aware of any community concerns regarding the site or its operation and administration? If so, please give details.

4. Are you aware of any events, incidents, or activities at the site such as vandalism, trespassing, or emergency responses from local authorities? If so, please give details.

5. Do you feel well informed about the site's activities and progress?

6. Do you have any comments, suggestions, or recommendations regarding the site's management or operation?

State and Local Considerations

State and local authorities may provide you with information about changes in State laws and regulations and present and prospective land uses and restrictions.

Interview	Information Sought
State Contacts (including those responsible for State water quality, hazardous waste, and environmental health issues)	– changes in State laws and regulations that may impact protectiveness – whether the site has been in compliance with permitting or reporting requirements – information on site activities, status, and issues
Local Authorities (such as police, emergency response or fire departments, and local environmental or planning offices)	– status of institutional controls, site access controls, new ordinances in place, changes in actual or projected land use, complaints being filed, and unusual activities at the site

Some example interview questions are given below.

1. What is your overall impression of the project? (general sentiment)

2. Have there been routine communications or activities (site visits, inspections, reporting activities, etc.) conducted by your office regarding the site? If so, please give purpose and results.

3. Have there been any complaints, violations, or other incidents related to the site requiring a response by your office? If so, please give details of the events and results of the responses.

4. Do you feel well informed about the site's activities and progress?

5. Do you have any comments, suggestions, or recommendations regarding the site's management or operation?

Construction Considerations

It is important for you to determine the status of construction at the site and to ensure that health and safety concerns are addressed.

Interview	Information Sought
Construction Contractor	– progress of project and changes in design due to field conditions – revisions to the O&M Manual, implementation of the Health and Safety Plan/Contingency Plan – insight into potential O&M problems
Construction Manager	– overview of all contractor construction activities at the site, health and safety issues, site protectiveness during construction, and the quality of the construction
Local Emergency Response Officials	– adequacy of contractor's Health and Safety Plan and the contractor's implementation of the Plan – adequacy of contractor's emergency response duties as outlined in the Contingency Plan or Emergency Response Plan of the Health and Safety Plan

Some example interview questions for remedial actions still under construction are given below.

1. What is your overall impression of the project? (general sentiment)

2. What is the current status of construction (*e.g.*, budget and schedule)?

3. Have any problems been encountered which required, or will require, changes to this remedial design or this ROD?

4. Have any problems or difficulties been encountered which have impacted construction progress or implementability?

5. Do you have any comments, suggestions, or recommendations regarding the project (i.e., design, construction documents, constructability, management, regulatory agencies, etc.)?

Performance, Operation And Maintenance Problems

The following individuals may provide information to you regarding the performance of the remedy and status of O&M at the site so that the team can assess the progress of the implementation and effectiveness of the remedy, and any O&M problems.

Interview	Information Sought
O&M Manager/Operating Contractor	– O&M status of the remedy, compliance with permit and reporting requirements, and complaints filed – effectiveness of the O&M Plan – information about any potential causes for concern about the remedy – progress and performance of the remedy
O&M Staff	– effectiveness of the O&M Manual – information about any potential causes for concern about the remedy – Recommendations for adjusting the mode of operation or optimizing the operations protocol
Remedial Design/Remedial Action Consultant	– original concepts behind the O&M of the remedy – questions about remedial design parameters, expected performance and cost, and changes that have occurred during implementation

Some example interview questions are given below.

1. What is your overall impression of the project? (general sentiment)

2. Is the remedy functioning as expected? How well is the remedy performing?

3. What does the monitoring data show? Are there any trends that show contaminant levels are decreasing?

4. Is there a continuous on-site O&M presence? If so, please describe staff and activities. If there is not a continuous on-site presence, describe staff and frequency of site inspections and activities.

5. Have there been any significant changes in the O&M requirements, maintenance schedules, or sampling routines since start-up or in the last five years? If so, do they affect the protectiveness or effectiveness of the remedy? Please describe changes and impacts.

6. Have there been unexpected O&M difficulties or costs at the site since start-up or in the last five years? If so, please give details.

7. Have there been opportunities to optimize O&M, or sampling efforts? Please describe changes and resultant or desired cost savings or improved efficiency.

8. Do you have any comments, suggestions, or recommendations regarding the project?

INTERVIEW DOCUMENTATION FORM

The following is a list of individual interviewed for this five-year review. See the attached contact record(s) for a detailed summary of the interviews.

Appendix D
Five-Year Review Site Inspection Checklist

[This page intentionally left blank.]

Five-Year Review Site Inspection Checklist

Purpose of the Checklist

The site inspection checklist provides a useful method for collecting important information during the site inspection portion of the five-year review. The checklist serves as a reminder of what information should to be gathered and provides the means of checking off information obtained and reviewed, or information not available or applicable. The checklist is divided into sections as follows:

I. Site Information
II. Interviews
III. On-site Documents & Records Verified
IV. O&M Costs
V. Access and Institutional Controls
VI. General Site Conditions
VII. Landfill Covers
VIII. Vertical Barrier Walls
IX. Groundwater/Surface Water Remedies
X. Other Remedies
XI. Overall Observations

Some data and information identified in the checklist may or may not be available at the site depending on how the site is managed. Sampling results, costs, and maintenance reports may be kept on site or may be kept in the offices of the contractor or at State offices. In cases where the information is not kept at the site, the item should not be checked as "not applicable," but rather it should be obtained from the office or agency where it is maintained. If this is known in advance, it may be possible to obtain the information before the site inspection.

This checklist was developed by EPA and the U.S. Army Corps of Engineers (USACE). It focuses on the two most common types of remedies that are subject to five-year reviews: landfill covers, and groundwater pump and treat remedies. Sections of the checklist are also provided for some other remedies. The sections on general site conditions would be applicable to a wider variety of remedies. The checklist should be modified to suit your needs when inspecting other types of remedies, as appropriate.

The checklist may be completed and attached to the Five-Year Review report to document site status. Please note that the checklist is not meant to be completely definitive or restrictive; additional information may be supplemented if the reviewer deems necessary. Also note that actual site conditions should be documented with photographs whenever possible.

Using the Checklist for Types of Remedies

The checklist has sections designed to capture information concerning the main types of remedies which are found at sites requiring five-year reviews. These remedies are landfill covers (Section VII of the checklist) and groundwater and surface water remedies (Section IX of the checklist). The primary elements and appurtenances for these remedies are listed in sections which can be checked off as the facility is inspected. The opportunity is also provided to note site conditions, write comments on the facilities, and attach any additional pertinent information. If a site includes remedies beyond these, such as soil vapor extraction or soil landfarming, the information should be gathered in a similar manner and attached to the checklist.

Considering Operation and Maintenance Costs

Unexpectedly widely varying or unexpectedly high O&M costs may be early indicators of remedy problems. For this reason, it is important to obtain a record of the original O&M cost estimate and of annual O&M costs during the years for which costs incurred are available. Section IV of the checklist provides a place for documenting annual costs and for commenting on unanticipated or unusually high O&M costs. A more detailed categorization of costs may be attached to the checklist if available. Examples of categories of O&M costs are listed below.

Operating Labor - This includes all wages, salaries, training, overhead, and fringe benefits associated with the labor needed for operation of the facilities and equipment associated with the remedial actions.

Maintenance Equipment and Materials - This includes the costs for equipment, parts, and other materials required to perform routine maintenance of facilities and equipment associated with a remedial action.

Maintenance Labor - This includes the costs for labor required to perform routine maintenance of facilities and for equipment associated with a remedial action.

Auxiliary Materials and Energy - This includes items such as chemicals and utilities which can include electricity, telephone, natural gas, water, and fuel. Auxiliary materials include other expendable materials such as chemicals used during plant operations.

Purchased Services - This includes items such as sampling costs, laboratory fees, and other professional services for which the need can be predicted.

Administrative Costs - This includes all costs associated with administration of O&M not included under other categories, such as labor overhead.

Insurance, Taxes and Licenses - This includes items such as liability and sudden and accidental insurance, real estate taxes on purchased land or right-of-way, licensing fees for certain technologies, and permit renewal and reporting costs.

Other Costs - This includes all other items which do not fit into any of the above categories.

[This page intentionally left blank.]

Please note that "O&M" is referred to throughout this checklist. At sites where Long-Term Response Actions are in progress, O&M activities may be referred to as "system operations" since these sites are not considered to be in the O&M phase while being remediated under the Superfund program.

Five-Year Review Site Inspection Checklist (Template)

(Working document for site inspection. Information may be completed by hand and attached to the Five-Year Review report as supporting documentation of site status. "N/A" refers to "not applicable.")

I. SITE INFORMATION	
Site name:	**Date of inspection:**
Location and Region:	**EPA ID:**
Agency, office, or company leading the five-year review:	**Weather/temperature:**

Remedy Includes: (Check all that apply)

G Landfill cover/containment
G Access controls
G Institutional controls
G Groundwater pump and treatment
G Surface water collection and treatment
G Monitored natural attenuation
G Groundwater containment
G Vertical barrier walls
G Other_____

_____

VII. LANDFILL COVERS G Applicable G N/A

A. Landfill Surface

1. **Settlement** (Low spots) G Location shown on site map G Settlement not evident
   Areal extent_____ Depth_____
   Remarks_____
   _____

2. **Cracks** G Location shown on site map G Cracking not evident
   Lengths_____ Widths_____ Depths_____
   Remarks_____
   _____

3. **Erosion** G Location shown on site map G Erosion not evident
   Areal extent_____ Depth_____
   Remarks_____
   _____

4. **Holes** G Location shown on site map G Holes not evident
   Areal extent_____ Depth_____
   Remarks_____
   _____

5. **Vegetative Cover** G Grass G Cover properly established G No signs of stress
   G Trees/Shrubs (indicate size and locations on a diagram)
   Remarks_____
   _____

6. **Alternative Cover (armored rock, concrete, etc.)** G N/A
   Remarks_____
   _____

7. **Bulges** G Location shown on site map G Bulges not evident
   Areal extent_____ Height_____
   Remarks_____
   _____

8. **Wet Areas/Water Damage** G Wet areas/water damage not evident
   G Wet areas G Location shown on site map Areal extent_____
   G Ponding G Location shown on site map Areal extent_____
   G Seeps G Location shown on site map Areal extent_____
   G Soft subgrade G Location shown on site map Areal extent_____
   Remarks_____

9. **Slope Instability** G Slides G Location shown on site map G No evidence of slope instability
   Areal extent_____
   Remarks_____

B. Benches G Applicable G N/A
(Horizontally constructed mounds of earth placed across a steep landfill side slope to interrupt the slope in order to slow down the velocity of surface runoff and intercept and convey the runoff to a lined channel.)

1. **Flows Bypass Bench** G Location shown on site map G N/A or okay
   Remarks_____

2. **Bench Breached** G Location shown on site map G N/A or okay
   Remarks_____

3. **Bench Overtopped** G Location shown on site map G N/A or okay
   Remarks_____

C. Letdown Channels G Applicable G N/A
(Channel lined with erosion control mats, riprap, grout bags, or gabions that descend down the steep side slope of the cover and will allow the runoff water collected by the benches to move off of the landfill cover without creating erosion gullies.)

1. **Settlement** G Location shown on site map G No evidence of settlement
   Areal extent_____ Depth_____
   Remarks_____

2. **Material Degradation** G Location shown on site map G No evidence of degradation
   Material type_____ Areal extent_____
   Remarks_____

3. **Erosion** G Location shown on site map G No evidence of erosion
   Areal extent_____ Depth_____
   Remarks_____

4. **Undercutting** G Location shown on site map G No evidence of undercutting
Areal extent_____ Depth_____
Remarks_____

5. **Obstructions** Type_____ G No obstructions
G Location shown on site map Areal extent_____
Size_____
Remarks_____

6. **Excessive Vegetative Growth** Type_____
G No evidence of excessive growth
G Vegetation in channels does not obstruct flow
G Location shown on site map Areal extent_____
Remarks_____

D. Cover Penetrations G Applicable G N/A

1. **Gas Vents** G Active G Passive
G Properly secured/lockedG Functioning G Routinely sampled G Good condition
G Evidence of leakage at penetration G Needs Maintenance
G N/A
Remarks_____

2. **Gas Monitoring Probes**
G Properly secured/lockedG Functioning G Routinely sampled G Good condition
G Evidence of leakage at penetration G Needs Maintenance G N/A
Remarks_____

3. **Monitoring Wells** (within surface area of landfill)
G Properly secured/lockedG Functioning G Routinely sampled G Good condition
G Evidence of leakage at penetration G Needs Maintenance G N/A
Remarks_____

4. **Leachate Extraction Wells**
G Properly secured/lockedG Functioning G Routinely sampled G Good condition
G Evidence of leakage at penetration G Needs Maintenance G N/A
Remarks_____

5. **Settlement Monuments** G Located G Routinely surveyed G N/A
Remarks_____

E. Gas Collection and Treatment G Applicable G N/A

1. **Gas Treatment Facilities**
   G Flaring G Thermal destruction G Collection for reuse
   G Good condition G Needs Maintenance
   Remarks_____

2. **Gas Collection Wells, Manifolds and Piping**
   G Good condition G Needs Maintenance
   Remarks_____

3. **Gas Monitoring Facilities** (*e.g.*, gas monitoring of adjacent homes or buildings)
   G Good condition G Needs Maintenance G N/A
   Remarks_____

F. Cover Drainage Layer G Applicable G N/A

1. **Outlet Pipes Inspected** G Functioning G N/A
   Remarks_____

2. **Outlet Rock Inspected** G Functioning G N/A
   Remarks_____

G. Detention/Sedimentation Ponds G Applicable G N/A

IX. GROUNDWATER/SURFACE WATER REMEDIES G Applicable G N/A

A. Groundwater Extraction Wells, Pumps, and Pipelines G Applicable G N/A

1. **Pumps, Wellhead Plumbing, and Electrical**
   G Good condition G All required wells properly operating G Needs Maintenance G N/A
   Remarks_____

2. **Extraction System Pipelines, Valves, Valve Boxes, and Other Appurtenances**
   G Good condition G Needs Maintenance
   Remarks_____

3. **Spare Parts and Equipment**
   G Readily available G Good condition G Requires upgrade G Needs to be provided
   Remarks_____

B. Surface Water Collection Structures, Pumps, and Pipelines G Applicable G N/A

1. **Collection Structures, Pumps, and Electrical**
   G Good condition G Needs Maintenance
   Remarks_____

2. **Surface Water Collection System Pipelines, Valves, Valve Boxes, and Other Appurtenances**
   G Good condition G Needs Maintenance
   Remarks_____

3. **Spare Parts and Equipment**
   G Readily available G Good condition G Requires upgrade G Needs to be provided
   Remarks_____

C. Treatment System G Applicable G N/A

1. **Treatment Train** (Check components that apply)
   G Metals removal G Oil/water separation G Bioremediation
   G Air stripping G Carbon adsorbers
   G Filters_____
   G Additive (*e.g.*, chelation agent, flocculent)_____
   G Others_____
   G Good condition G Needs Maintenance
   G Sampling ports properly marked and functional
   G Sampling/maintenance log displayed and up to date
   G Equipment properly identified
   G Quantity of groundwater treated annually_____
   G Quantity of surface water treated annually_____
   Remarks_____
   _____

2. **Electrical Enclosures and Panels** (properly rated and functional)
   G N/A G Good condition G Needs Maintenance
   Remarks_____
   _____

3. **Tanks, Vaults, Storage Vessels**
   G N/A G Good condition G Proper secondary containment G Needs Maintenance
   Remarks_____
   _____

4. **Discharge Structure and Appurtenances**
   G N/A G Good condition G Needs Maintenance
   Remarks_____
   _____

5. **Treatment Building(s)**
   G N/A G Good condition (esp. roof and doorways) G Needs repair
   G Chemicals and equipment properly stored
   Remarks_____
   _____

6. **Monitoring Wells** (pump and treatment remedy)
   G Properly secured/lockedG Functioning G Routinely sampled G Good condition
   G All required wells located G Needs Maintenance G N/A
   Remarks_____
   _____

D. Monitoring Data

1. Monitoring Data
   G Is routinely submitted on time G Is of acceptable quality

2. Monitoring data suggests:
   G Groundwater plume is effectively contained G Contaminant concentrations are declining

D. Monitored Natural Attenuation

1. **Monitoring Wells** (natural attenuation remedy)
G Properly secured/lockedG Functioning G Routinely sampled G Good condition
G All required wells located G Needs Maintenance G N/A
Remarks_____

X. OTHER REMEDIES

If there are remedies applied at the site which are not covered above, attach an inspection sheet describing the physical nature and condition of any facility associated with the remedy. An example would be soil vapor extraction.

XI. OVERALL OBSERVATIONS

A. Implementation of the Remedy

Describe issues and observations relating to whether the remedy is effective and functioning as designed. Begin with a brief statement of what the remedy is to accomplish (i.e., to contain contaminant plume, minimize infiltration and gas emission, etc.).

B. Adequacy of O&M

Describe issues and observations related to the implementation and scope of O&M procedures. In particular, discuss their relationship to the current and long-term protectiveness of the remedy.

C.	**Early Indicators of Potential Remedy Problems**
	Describe issues and observations such as unexpected changes in the cost or scope of O&M or a high frequency of unscheduled repairs, that suggest that the protectiveness of the remedy may be compromised in the future.
D.	**Opportunities for Optimization**
	Describe possible opportunities for optimization in monitoring tasks or the operation of the remedy.

Appendix E
Five-Year Review Report Template

[This page intentionally left blank.]

Five-Year Review Report Template

This appendix provides a suggested checklist and a format for Five-Year Review reports. The checklist appears first, followed by the report template. You are encouraged to follow the template to ensure national consistency in the structure of Five-Year Review reports. However, each report should take into account site-specific circumstances, and you should modify the report format and content accordingly. For example, in some cases the report may be clearer if organized by operable unit (OU), or you may need to include site-specific questions that do not appear in this appendix.

The suggested format for Five-Year Review reports includes three main components: cover material, summary information, and the report body. Templates for each of these components follow. These templates provide suggested standard formats, boilerplate text, subheadings, checklists, example tables, and protectiveness statements. Suggested boilerplate text is presented in text boxes. Within the boilerplate section, text enclosed in brackets ("[ ]") should be added as appropriate, and *italicized* text denotes discussions that the reviewer should add.

You should use both the checklist and report template as guides for the types of information that should appear in the different sections of your Five-Year Review report. You should include information that is relevant to your site and needed to ensure that the rationale behind the protectiveness determination is adequately documented.

[This page intentionally left blank.]

Content Checklist For Five-Year Review Reports

This checklist may be used by you, your managers, etc., to verify that you have included all of the appropriate information in your Five-Year Review report. Depending on site-specific circumstances, some items may not be applicable. For example, a report for a site just beginning construction will generally contain less data than for a site that has reached construction completion.

General Report Format

- ☐ Signed concurrence memorandum (as appropriate)
- ☐ Title page with signature and date
- ☐ Completed five-year review summary form (page E-15)
- ☐ List of documents reviewed
- ☐ Site maps (as appropriate)
- ☐ List of tables and figures
- ☐ Interview report (as appropriate)
- ☐ Site inspection checklist
- ☐ Photos documenting site conditions (as appropriate)

Introduction

- ☐ The purpose of the five-year review
- ☐ Authority for conducting the five-year review
- ☐ Who conducted the five-year review (lead agency) and when
  - ☐ Organizations providing analyses in support of the review (*e.g.*, the contractor supporting the lead agency)
  - ☐ Other review participants or support agencies
- ☐ Review number (*e.g.*, first, second)
- ☐ Trigger action and date
- ☐ Number, description, and status of all operable units at the site
- ☐ If review covers only part of a site, explain approach
  - ☐ Define which areas are covered in the five-year review
  - ☐ Summarize the status of other areas of the site that are not covered in the present five-year

Site Chronology

- ☐ List all important site events and relevant dates (*e.g.*, date of initial discovery of problem, dates of pre-NPL responses, date of NPL listing, etc.)

Background

- ☐ General site description (*e.g.*, size, topography, and geology)
- ☐ Former, current, and future land use(s) of the site and surrounding areas
- ☐ History of contamination
- ☐ Initial response (*e.g.*, removals)
- ☐ Basis for taking remedial action (*e.g.*, contaminants)

Remedial Actions

- ☐ Regulatory actions (*e.g.*, date and description of Records of Decision, Explanations of Significant Difference, Administrative Orders on Consent, Consent Decrees and Action Memorandum)
- ☐ Remedial action objectives
- ☐ Remedy description
- ☐ Remedy implementation (*e.g.*, status, history, enforcement actions, performance)
- ☐ Systems operations/Operations & Maintenance
  - ☐ Systems operations/O&M requirements
  - ☐ Systems operations/O&M operational summary (*e.g.*, history, modifications, problems, and successes)
  - ☐ Summary of costs of system operations/O&M effectiveness (*i.e.*, are requirements being met and are activities effective in maintaining the remedy?)

Progress Since Last Five-Year Review (if applicable)

- ☐ Protectiveness statements from last review
- ☐ Status of recommendations and follow-up actions from last review
- ☐ Results of implemented actions, including whether they achieved the intended effect
- ☐ Status of any other prior issues

Five-Year Review Process

- ☐ Administrative Components
  - ☐ Notification of potentially interested parties of initiation of review process
  - ☐ Identification of five-year review team members (as appropriate)
  - ☐ Outline of components and schedule of your five-year review
- ☐ Community Involvement
  - ☐ Community notification (prior and post review)
  - ☐ Other community involvement activities (*e.g.*, notices, fact sheets, etc., as appropriate)
- ☐ Document review
- ☐ Data review
- ☐ Site inspection
  - ☐ Inspection date
  - ☐ Inspection participants

Five-Year Review Process, cont'd.

- ☐ Site inspection scope and procedures
- ☐ Site inspection results, conclusions
- ☐ Inspection checklist

☐ Interviews

- ☐ Interview date(s) and location(s)
- ☐ Interview participants (name, title, etc.)
- ☐ Interview documentation
- ☐ Interview summary

Technical Assessment

☐ Answer Question A: Is the remedy functioning as intended by the decision documents?

- ☐ remedial action performance (*i.e.*, is the remedy operating as designed?)
- ☐ system operations/O&M
- ☐ cost of system operations/O&M
- ☐ opportunities for optimization
- ☐ early indicators of potential issues
- ☐ implementation of institutional controls and other measures

☐ Answer Question B: Are the exposure assumptions, toxicity data, cleanup levels, and remedial action objectives (RAOs) used at the time of the remedy selection still valid?

- ☐ changes in standards, newly promulgated standards, TBCs
- ☐ expected progress towards meeting RAOs
- ☐ changes in exposure pathways
- ☐ changes in land use
- ☐ new contaminants and/or contaminant sources
- ☐ remedy byproducts
- ☐ changes in toxicity and other contaminant characteristics
- ☐ risk recalculation/assessment (as applicable)

☐ Answer Question C: Has any other information come to light that could call into question the protectiveness of the remedy?

- ☐ new or previously unidentified ecological risks
- ☐ natural disaster impacts
- ☐ any other information that could call into question the protectiveness of the remedy

☐ Technical Assessment Summary

Issues

- ☐ Issues identified during the technical assessment and other five-year review activities
- ☐ Determination of whether issues affect current or future protectiveness

Issues, cont'd.

- ☐ A discussion of unresolved issues raised by support agencies and the community (States, Tribes, other Federal agencies, local governments, citizens, PRPs, other interested parties), if applicable

Recommendations and Follow-up Actions

- ☐ Required/suggested improvements to identified issues or to current site operations
- ☐ Note parties responsible for actions
- ☐ Note agency with oversight authority
- ☐ Schedule for completion of actions related to resolution of issues

Protectiveness Statements

- ☐ Protective statement(s) for each OU (If the remedy is not protective of human health and/or the environment, have you provided supporting discussion and information in the report to make this determination, such as current threats or level of risk?)
- ☐ Comprehensive protectiveness statement covering all of the remedies at the site (if applicable)

Next Review

- ☐ Expected date of next review
- ☐ If five-year reviews will no longer be done, provide a summary of that portion of the technical analysis presented in the report that provides the rationale for discontinuation of five-year reviews

Five-Year Review Report

Five-Year Review Report

The following Table of Contents notes typical major divisions and subheadings for Five-Year Review reports. Subheadings can be included as appropriate for a given review report. This is only a general example.

Table of Contents

Tables

Attachments

Appendix

List of Acronyms

You should include a list of acronyms used in the report here.

[This page intentionally left blank.]

Executive Summary

You should include an Executive Summary at the beginning of the report. The Executive Summary should be brief, and should include a reiteration of the protectiveness statements included in Section X of the Five-Year Review report.

[This page intentionally left blank.]

Five-Year Review Summary Form

SITE IDENTIFICATION

Site name ***(from WasteLAN)*****:**

EPA ID ***(from WasteLAN)*****:**

Region:	**State:**	**City/County:**

SITE STATUS

NPL status: G Final G Deleted G Other (specify) _____

Remediation status (choose all that apply): G Under Construction G Operating G Complete

Multiple OUs?* G YES G NO	**Construction completion date:** ___ / ___ / _____

Has site been put into reuse? G YES G NO

REVIEW STATUS

Lead agency: G EPA G State G Tribe G Other Federal Agency _____

Author name:

Author title:	**Author affiliation:**

Review period:** ___ / ___ / _____ to ___ / ___ / _____

Date(s) of site inspection: ___ / ___ / _____

Type of review:

G Post-SARA G Pre-SARA G NPL-Removal only
G Non-NPL Remedial Action Site G NPL State/Tribe-lead
G Regional Discretion

Review number: G 1 (first) G 2 (second) G 3 (third) G Other (specify) _____

Triggering action:

G Actual RA Onsite Construction at OU #____ G Actual RA Start at OU#____
G Construction Completion G Previous Five-Year Review Report
G Other (specify) _____

Triggering action date ***(from WasteLAN)*****:** ___ / ___ / _____

Due date ***(five years after triggering action date)*****:** ___ / ___ / _____

* ["OU" refers to operable unit.]
** [Review period should correspond to the actual start and end dates of the Five-Year Review in WasteLAN.]

Five-Year Review Summary Form, cont'd.

Issues:

Summarize issues (see Chapter 3).

Recommendations and Follow-up Actions:

Summarize recommendations and follow-up actions (see Chapter 3).

Protectiveness Statement(s):

Include individual operable unit protectiveness statements. For sites that have reached construction completion and have more than one OU, include an additional and comprehensive protectiveness statement covering all of the remedies at the site (see Chapter 4).

Other Comments:

Make any other comments here.

Five-Year Review Report

I. Introduction

Provide a synopsis of "who, what, where, when, and why." Detail the following:

- *The purpose of the review;*
- *The authority for conducting the five-year review;*
- *Who conducted the review, when, and for what site or portion of the site;*
- *Whether it is the first review or a subsequent review at the site;*
- *What action triggered the review; and*
- *A brief status of areas of a site not addressed in the current review and/or the status of five-year reviews for other areas of the entire site.*

Further explanation and boilerplate text are provided below. Additional explanation on the following topics is provided in Chapter 1.

The Purpose of the Review

State the purpose of the five-year review specific to the site or portion of the site addressed in the review.

The purpose of five-year reviews is to determine whether the remedy at a site [is/is expected to be] protective of human health and the environment. The methods, findings, and conclusions of reviews are documented in Five-Year Review reports. In addition, Five-Year Review reports identify issues found during the review, if any, and recommendations to address them.

Authority for Conducting the Five-Year Review

The Agency is preparing this five-year review pursuant to CERCLA §121 and the National Contingency Plan (NCP). CERCLA §121 states: *If the President selects a remedial action that results in any hazardous substances, pollutants, or contaminants remaining at the site, the President shall review such remedial action no less often than each five years after the initiation of such remedial action to assure that human health and the environment are being protected by the remedial action being implemented. In addition, if upon such review it is the judgment of the President that action is appropriate at such site in accordance with section [104]*

> *or [106], the President shall take or require such action. The President shall report to the Congress a list of facilities for which such review is required, the results of all such reviews, and any actions taken as a result of such reviews.*
>
> The agency interpreted this requirement further in the National Contingency Plan (NCP); 40 CFR §300.430(f)(4)(ii) states:
>
> *If a remedial action is selected that results in hazardous substances, pollutants, or contaminants remaining at the site above levels that allow for unlimited use and unrestricted exposure, the lead agency shall review such action no less often than every five years after the initiation of the selected remedial action.*

Who Conducted the Five-Year Review

If the U.S. Army Corps of Engineers (USACE) or a contractor has conducted an analysis in support of a five-year review, you should include their name and the date of the analysis. When a contractor for a potentially responsible party (PRP) conducts analyses or provides information in support of a five-year review, you should identify the a contractor and their affiliation with the PRP in the Five-Year Review report. You should also identify who conducted the site inspection.

Boilerplate text for the explanation of who conducted the review is provided in the box below. This text is written as though EPA is the lead agency and should be adapted when another agency or department serves as the lead agency.

> The United States Environmental Protection Agency (EPA) Region [number] has conducted a five-year review of the remedial actions implemented at the [name] site in [location]. This review was conducted from [month, year] through [month, year]. This report documents the results of the review. [Please identify any party providing an analysis in support of the five-year review; also indicate the contractual arrangements under which this was done.]

Other Review Characteristics

State whether the review is the first or a subsequent five-year review for the site, what action or event "triggered" the review, and the date of this action. See Chapter 1, Section 1.2 of this guidance for a discussion of triggering events for the five-year review and indicate in your report whether the trigger for the current five-year review has been met.

Boilerplate text for the explanation of other review characteristics is provided in the box below. Select text from brackets as appropriate.

This is the [first/second/etc.] five-year review for the [name] site. The triggering action for this review is the date of the [triggering action], as shown in EPA's WasteLAN database: [date]. [This discussion should also mention what is specifically activating the review, *i.e.*, that hazardous substances, pollutants, or contaminants are or will be left on site above levels that allow for unlimited use and unrestricted exposure.]

In addition, if separate five-year reviews are conducted for different areas of a site, you should include the following in this section:

- *An explanation of this approach;*
- *A description of which areas are covered by this five-year review; and*
- *A brief synopsis of the remedial activities and the status of remedial measures and/or five-year reviews for other areas.*

II. Site Chronology

List all important site events and relevant dates in the site chronology, such as those shown in Table 1. The identified events are illustrative, not comprehensive.

Table 1: Chronology of Site Events

Event	Date
Initial discovery of problem or contamination	
Pre-NPL responses	
NPL listing	
Removal actions	
Remedial Investigation/Feasibility Study complete	
ROD signature	
ROD Amendments or ESDs	
Enforcement documents (CD, AOC, Unilateral Administrative Order)	
Remedial design start	
Remedial design complete	

Table 1: Chronology of Site Events

Event	Date
Superfund State Contract, Cooperative Agreement, or Federal Facility Agreement signature	
Actual remedial action start	
Construction dates (start, finish)	
Construction completion date	
Final Close-out Report	
Deletion from NPL	
Previous five-year reviews	

III. Background

Describe the fundamental aspects of the site, providing a clear, succinct description of site characteristics. The purpose of this section is to identify the threat posed to the public and environment at the time of the ROD, so that the performance of the remedy can be easily compared with the site conditions the remedy was intended to address. Include all major site activities prior to the signing of the ROD. In addition to text, you may use site maps to help clarify the discussion. The following checklist may assist you in developing the text for this section.

	Background Checklist
Physical Characteristics *Present the site's location and characteristics, including the following:*	
	Area of site, relation to parcel(s), extent and location of sources
	Whether site is located in a populated area or is near populated areas
	Whether site is located in an environmentally sensitive area or is near environmentally sensitive areas, where applicable
Land and Resource Use *Discuss the following:*	
	Former, current and projected land uses for the site, as identified in the ROD or other decision document
	Current and projected land uses for the area surrounding the site, at the time of the five-year review
	Human and ecological past, present and known future use of resources (*e.g.*, groundwater or surface water as a drinking water supply) and any other current uses of the site not already addressed, as applicable

	Background Checklist
History of Contamination *Discuss the following:*	
	The historical activities that caused contamination, including the type of activity or process, when it took place, the specific type of hazardous substances, and their volumes/proportions, if known
	How contamination was discovered and problems resulting from contamination
Initial Response *Describe any pre-ROD cleanup activities at the site:*	
	CERCLA removal actions, non-CERCLA removals/responses, closures, the ceasing of operations, as well as governing agreements and parties involved in these activities
Basis for Taking Action *Describe the contaminants found at the site by appropriate media type (soil, groundwater, surface water, air). Note the effect or potential effect of the contamination on people, resources they use, or the environment. Examples of elements of this discussion include the following:*	
	Contaminated media and structures (summary of remedial investigation)
	Resources/targets that have been or could potentially be affected, results of risk assessments, determination of primary health threat

IV. Remedial Actions

Discuss initial plans, implementation history, and current status of the remedy. Explain events identified in the chronology, and generally include discussions of remedy selection, remedy implementation, remedy performance, and system operations/O&M. Present – accurately, adequately, and concisely – relevant site activities from the signing of the ROD to the present. You should delineate all remedial measures, for instance, include monitoring, fencing, and institutional controls. Discuss any changes to or problems with remedial components. The following checklist may assist you in developing the text for this section.

	Remedial Actions Checklist
Remedy Selection *Describe the remedial action objectives and the selected remedy. This discussion should explain the following:*	
	Scope and role of actions including definition of OUs related to each ROD and how they relate to each other
	Source documents listing remedial action objectives and the remedy (e.g., RODs, ESDs), including signature/filing date
	Statement of remedial action objectives, related to each OU or ROD
	Description of remedial actions/remedy, related to each OU or ROD, noting media addressed; all components of the remedy, including engineering controls, access controls, institutional controls, cleanup measures, treatment types, and required monitoring should be described

	Remedial Actions Checklist
Remedy Implementation *Discuss the history of and plans for implementation of the remedy. Discuss enforcement actions if applicable. The text may be presented either chronologically or by OU, and should include the following:*	
	Dates when remedial designs were started and completed
	Difficulties or changes that occurred during remedial design
	Dates when remedial actions were started and completed
	The performance of each remedial action since implementation
	Enforcement agreements, and parties involved in these agreements
	CERCLA removal actions or non-CERCLA removals/responses since the ROD
System Operations/O&M *Describe system operations/O&M requirements, activities to date, any problems that have arisen, and costs:*	
	System operations/O&M requirements, as noted in the system operations/O&M plan, system operations/O&M manual, enforcement documents, and monitoring plans
	System operations/O&M activities to date
	Problems in the implementation of system operations/O&M
	Originally estimated annual O&M costs
	Actual annual O&M costs over the review period
	Reasons for any unanticipated or unusually high O&M costs

A table, such as Table 2, should be used to document total annual system operations/O&M costs during the period preceding the current five-year review. In the text, you should discuss significant variations from anticipated costs or between operating years.

Table 2: Annual System Operations/O&M Costs

Dates		Total Cost rounded to nearest $1,000
From	To	

At the end of the remedial actions section, it is sometimes helpful for you to add a brief discussion of the current status of each of the components of the remedy. This discussion can be particularly helpful for large, complex sites.

V. Progress Since the Last Review

Progress since the last review should be discussed when follow-up actions which impact protectiveness were noted in the previous Five-Year Review report. The following checklist may assist you in developing the text for this section.

	Progress Since the Last Review Checklist
Describe progress toward accomplishing recommendations and follow-up actions since the last five-year review was completed. Include the following:	
	Protectiveness statements from the last review
	Status of recommendations and follow-up actions from last review
	Results of implemented actions, including whether they achieved the intended effect
	Status of any other prior issues

Table 3 below presents one approach for providing information on the recommendations and follow-up actions stated in the past review and subsequent actions. The accompanying text should also discuss why any recommendations and follow-up actions have not been implemented if that is the case, and whether implemented actions achieved desired results.

Table 3: Actions Taken Since the Last Five-Year Review

Issues from Previous Review	Recommendations/ Follow-up Actions	Party Responsible	Milestone Date	Action Taken and Outcome	Date of Action

VI. Five-Year Review Process

Describe activities performed during the five-year review process and provide a summary of findings when appropriate. The following checklist may assist you in developing the text for this section.

	Five-Year Review Process Checklist
Administrative Components of the Five-Year Review Process	
	Notify potentially interested parties of start of five-year review
	Identify members of the review team
	Develop a review schedule

	Five-Year Review Process Checklist
Community Notification and Involvement	
	Community notification
	Other community involvement activities
Document Review See Appendix B for a full discussion of the document review	
	What documents were reviewed
	Identify document source of RAOs, ARARs and cleanup levels
Data Review *Discuss and present the following:*	
	What data were reviewed
	Relevant trends and levels, noting levels which are not currently compliant and whether future compliance can be expected without additional action
	Tables summarizing monitoring and sampling data
	Increase and/or decrease or non-presence of specific chemical compounds and recommended changes for future monitoring programs
Site Inspection *Summarize the site inspection and site conditions:*	
	Date of site inspection (if more than one inspection was conducted to allow for monitoring or further inspection, list all inspections and activities conducted, and the reasons for conducting each inspection)
	Who conducted and/or attended the inspection
	Activities conducted (scope and procedures)
	Summary of site conditions, inspection results, conclusions
Interviews *Discuss the following:*	
	Interviews conducted (name, title, organization, date, location(S))
	Interview documentation
	Interview summary
	Successes/problems in the implementation of access and institutional controls
	Successes/problems with the construction of the remedy
	Successes/problems with system operations/O&M
	Unusual situations or problems at the site

VII. Technical Assessment

Discuss how each of the three questions asked in the technical assessment were answered (e.g., yes, yes, no or a variation of this) and provide the information that presents the basis for each answer as a framework for your protectiveness determination(s). Explain the conclusions of

your review, based on the information presented in the previous section. As explained in Chapter 4, the assessment should focus on answering three key questions:

- *Question A: Is the remedy functioning as intended by the decision documents?*
- *Question B: Are the exposure assumptions, toxicity data, cleanup levels, and remedial action objectives (RAOs) used at the time of remedy selection still valid?*
- *Question C: Has any other information come to light that could call into question the protectiveness of the remedy?*

Each question, and the associated information to be discussed, is presented in its own checklist which may assist you in developing the text for this section. Checklist items shown may be supplemented or modified based on site-specific circumstances.

	Checklist for Question A: Is the remedy functioning as intended by the decision documents?
Remedial Action Performance *Discuss the following:*	
	Whether the remedial action continues to be operating and functioning as designed
	Whether the remedial action is performing as expected and cleanup levels are being achieved
	Whether containment is effective
System Operations/O&M *Discuss the following:*	
	Whether operating procedures, as implemented, will maintain the effectiveness of response actions
	Whether large variances in O&M costs could indicate a potential remedy problems or remedy issues
Opportunities for Optimization *Discuss the following:*	
	Whether opportunities exist to improve the performance and/or reduce costs of monitoring, sampling, and treatment systems
Early Indicators of Potential Issues *Discuss the following:*	
	Whether frequent equipment breakdowns or changes indicate a potential issue
	Whether issues or problems could place protectiveness at risk
Implementation of Institutional Controls and Other Measures *Discuss the following:*	
	Whether access controls are in place and prevent exposure (*e.g.*, fencing and warning signs)
	Whether institutional controls are in place and prevent exposure
	Whether other actions (*e.g.*, removals) necessary to ensure that immediate threats have been addressed are complete

	Checklist for Question B: Are the exposure assumptions, toxicity data, cleanup levels, and remedial action objectives (RAOs) used at the time of remedy selection still valid?
Changes in Standards and TBCs *Discuss the following:*	
	Whether standards identified in the ROD have been revised and call into question the protectiveness of the remedy
	Whether newly promulgated standards call into question the protectiveness of the remedy
	Whether TBCs used in selecting cleanup levels at the site have changed and could affect the protectiveness of the remedy
Changes in Exposure Pathways *Discuss the following:*	
	Whether land use or expected land use on or near the site changed
	Whether human health or ecological routes of exposure or receptors have been newly identified or changed in a way that could affect the protectiveness of the remedy
	Whether there are newly identified contaminants or contaminant sources
	Whether there are unanticipated toxic byproducts of the remedy not previously addressed by the decision documents
	Whether physical site conditions or the understanding of these conditions have changed in a way that could affect the protectiveness of the remedy
Changes in Toxicity and Other Contaminant Characteristics *Discuss the following:*	
	Whether toxicity factors for contaminants of concern at the site have changed in a way that could affect the protectiveness of the remedy
	Whether other contaminant characteristics have changed in a way that could affect the protectiveness of the remedy
Changes in Risk Assessment Methods *Discuss the following:*	
	Whether standardized risk assessment methodologies have changed in a way that could affect the protectiveness of the remedy
Expected Progress Towards Meeting RAOs	
	Whether the remedy is progressing as expected

When a standard or requirement has changed, a table can be used to record the nature of the change. Tables 4, 5, and 6 below demonstrate potential ways for you to note changes in chemical-specific, action-specific, or location-specific requirements, respectively.

Table 4: Changes in Chemical-Specific Standards

Contaminant	Media	Cleanup Level	Standard		Citation/Year
Chemical A	*e.g.*, groundwater	*e.g.*, 0.XX mg/L	Previous	*e.g.*, 0.XX mg/L	*e.g.*, SDWA 1988
			New	*e.g.*, 0.YY mg/L	*e.g.*, SDWA 1995
Chemical B			Previous		
			New		

Table 5: Changes in Action-Specific Requirements

Action	Requirement		Prerequisite	Citation/Year
Action A (*e.g.*, landfill)	Previous	Include original ARAR here; if none applies, state "None"		
	New			

Table 6: Changes in Location-Specific Requirements

Location	Requirement		Prerequisite	Citation/Year
Location A (*e.g.*, critical habitat upon which endangered or threatened species depend)	Previous	Include original ARAR here; if none applies, state "None"		
	New			

	Checklist for Question C: Has any other information come to light that could call into question the protectiveness of the remedy?
Other Information *Discuss the following:*	
	Whether newly identified ecological risks been found
	Whether there are impacts from natural disasters
	Whether any other information has come to light which could affect the protectiveness of the remedy

Technical Assessment Summary

Discuss how each of the three questions were answered and provide the information that presents the basis for each answer as a framework for your protectiveness determination(s).

VIII. Issues

Detail issues related to current site operations, conditions, or activities, noting which issue, if any, currently prevent the remedy from being protective. You may use a table such as Table 7 to note the issues identified.

Table 7: Issues

Issues	Affects Current Protectiveness (Y/N)	Affects Future Protectiveness (Y/N)

IX. Recommendations and Follow-up Actions

Specify the required and suggested improvements to current site operations, activities, remedy, or conditions. Note the parties responsible for actions, milestone dates, and which agencies have oversight authority. At a minimum, address all issues that currently affect current and/or future protectiveness. Table 8 illustrates one way to include the necessary information.

Table 8: Recommendations and Follow-up Actions

Issue	Recommendations and Follow-up Actions	Party Responsible	Oversight Agency	Milestone Date	Affects Protectiveness (Y/N)	
					Current	Future

X. Protectiveness Statement(s)

Include a protectiveness statement for each OU at which a remedial action has begun. For sites that have reached construction completion and have more than one OU, you should develop and include an additional comprehensive site-wide protectiveness statement covering all of the remedies at the site. You should not include this additional protectiveness statement until construction completion because, until then, all remedies at the site have not necessarily been selected and constructed.

In order to promote consistency, you are strongly encouraged to model your protectiveness statements on the sample protectiveness statements provided in Chapter 4, Exhibits 4-6 and 4-7. Your Five-Year Review report should present the protectiveness statements at the beginning of a

discussion that should explain and provide the supporting rationale of the protectiveness determination.

Suggested statements are as follows:

If the remedial action at the OU is under construction, then use this statement:

Protective or will be protective:

"The remedy at OU X is expected to be protective of human health and the environment upon completion, and in the interim, exposure pathways that could result in unacceptable risks are being controlled."

Not protective:

"The remedy at OU X is not protective because of the following issues [describe the issue(s)]. The following actions need to be taken [describe the actions needed to ensure protectiveness]."

Protectiveness deferred:

"A protectiveness determination of the remedy at OU X cannot be made at this time until further information is obtained. Further information will be obtained by taking the following actions [describe the actions]. It is expected that these actions will take approximately [insert time frame] to complete, at which time a protectiveness determination will be made."

If the remedial action at the OU is operating or completed:

Protective:

"The remedy at OU X is expected to be or is protective of human health and the environment, and in the interim, exposure pathways that could result in unacceptable risks are being controlled."

Protective in the short-term:

"The remedy at OU X currently protects human health and the environment because [describe the elements of the remedy that protect human health and the environment in the short term]. However, in order for the remedy to be protective in the long-term, the following actions need to be taken [describe the actions needed to ensure long-term protectiveness]."

Not protective:

"The remedy at OU X is not protective because of the following issue(s) [describe the issue(s)]. The following actions need to be taken [describe the actions needed to ensure protectiveness].

Protectiveness deferred:

"A protectiveness determination of the remedy at OU X cannot be made at this time until further information is obtained. Further information will be obtained by taking the following actions [describe the actions]. It is expected that these actions will take approximately [insert time frame] to complete, at which time a protectiveness determination will be made."

For Sites That Have Reached Construction Completion:

If the remedy(s) is/are protective then use:

"Because the remedial actions at all OUs are protective, the site is protective of human health and the environment."

If the remedy is not protective then use:

"The remedial actions at OUs X and Y are protective. However, because the remedial action at OU Z is not protective, the site is not protective of human health and the environment at this time. The remedial action at OU Z is not protective because of the following issue(s) [describe the issue(s)]. The following actions need to be taken [describe the actions needed to ensure protectiveness]."

XI. Next Review

Discuss whether another five-year review will be conducted and the date on which that report will be due. If no additional five-year reviews are to be conducted, explain why and provide a justification for discontinuation of reviews.

Executive Summary

The remedy for the Acme Superfund site in Riverside, Massachusetts included stabilization and capping of contaminated soils and sediments on site, institutional controls, and monitored natural attenuation of contaminated groundwater. The site achieved construction completion with the signing of the Preliminary Close Out Report on August 28, 1998. The trigger for this five-year review was the actual start of construction on September 12, 1995.

The assessment of this five-year review found that the remedy was constructed in accordance with the requirements of the Record of Decision (ROD). One Explanation of Significant Difference (ESD) was issued to change the cap design and the treatment approach of soils and sediments. The remedy is functioning as designed. The immediate threats have been addressed and the remedy is expected to be protective when groundwater cleanup goals are achieved through monitored natural attenuation, which is expected to require 10 years.

Due date *(five years after triggering action date)*: 9 / 12 / 2000		

* ["OU" refers to operable unit.]

** [Review period should correspond to the actual start and end dates of the Five-Year Review in WasteLAN.]

Five-Year Review Summary Form, cont'd.

Issues:

Burrowing animals were observed to have left minor tunnels in cap soil, and a portion of the constructed wetlands have not been properly maintained.

Failure to maintain a portion of the constructed wetlands due to restricted access to the property.

Inadequate monitoring to verify that the plume is not migrating.

Recommendations and Follow-up Actions:

The burrows are scheduled to be repaired. The State and Potentially Settling Defendants (PSDs) are actively seeking an alternate location for wetlands development.

Identify an alternate location for wetlands development.

Increase monitoring frequency for MW-103; Investigate groundwater discharge to river; sample sediments and groundwater at discharge points.

Protectiveness Statement(s):

All immediate threats at the site have been addressed, and the remedy is expected to be protective of human health and the environment after the groundwater cleanup goals are achieved through MNA in an estimated 10 years.

Long-term Protectiveness:

Long-term protectiveness of the remedial action will be verified by obtaining additional groundwater samples to fully evaluate potential migration of the contaminant plume downgradient from the treatment area and towards the river. Current data indicate that the plume remains on site. Additional sampling and analysis will be completed within the next six months. Current monitoring data indicate that the remedy is functioning as required to achieve groundwater cleanup goals.

Other Comments:

The problems encountered in maintaining the wetlands result from access issues that will be resolved once an alternative location for development of wetlands is identified. This issue does not impact protectiveness and is expected to be resolved within the current year.

Acme Superfund Site
Riverside, Massachusetts
First Five-Year Review Report

I. Introduction

The purpose of the five-year review is to determine whether the remedy at a site is protective of human health and the environment. The methods, findings, and conclusions of reviews are documented in Five-Year Review reports. In addition, Five-Year Review reports identify issues found during the review, if any, and identify recommendations to address them.

The Agency is preparing this Five-Year Review report pursuant to CERCLA §121 and the National Contingency Plan (NCP). CERCLA §121 states:

> *If the President selects a remedial action that results in any hazardous substances, pollutants, or contaminants remaining at the site, the President shall review such remedial action no less often than each five years after the initiation of such remedial action to assure that human health and the environment are being protected by the remedial action being implemented. In addition, if upon such review it is the judgement of the President that action is appropriate at such site in accordance with section [104] or [106], the President shall take or require such action. The President shall report to the Congress a list of facilities for which such review is required, the results of all such reviews, and any actions taken as a result of such reviews.*

The Agency interpreted this requirement further in the NCP; 40 CFR §300.430(f)(4)(ii) states:

> *If a remedial action is selected that results in hazardous substances, pollutants, or contaminants remaining at the site above levels that allow for unlimited use and unrestricted exposure, the lead agency shall review such action no less often than every five years after the initiation of the selected remedial action.*

The United States Environmental Protection Agency (EPA), Region 1, conducted the five-year review of the remedy implemented at the Acme Superfund Site in Riverside, Massachusetts. This review was conducted by the Remedial Project Manager (RPM) for the entire site from March 2000 through August 2000. This report documents the results of the review.

This is the first five-year review for the Acme Site. The triggering action for this statutory review is the initiation of the remedial action on September 12, 1995. The five-year review is required due to the fact that hazardous substances, pollutants, or contaminants remain at the site above levels that allow for unlimited use and unrestricted exposure.

II. Site Chronology

Table 1 - Chronology of Site Events

Event	Date
Waste oil and solvent recovery activities at the site	1974 - 1978
Massachusetts Department of Environmental Quality Engineering (DEQE) (now Massachusetts Department of Environmental Protection or MADEP), initiates actions against facility owners resulting in closing of facility	1978
Removal activities - removing drums, liquids and sludge from tanks	1978 - 1984
Final listing on EPA National Priorities List	9/1983
Interim removal activities - Demolition and removal of remaining storage tanks and waste material contained in tanks	1986
Remedial Investigation/Feasibility Study (RI/FS) made available to public	1/1992
Proposed plan identifying EPA's preferred remedy presented to public; start of public comment period.	3/1992
ROD selecting the remedy is signed	9/30/1992
Consent Decree finalizing settlement for responsible party performance of remedy entered by Federal Court	9/18/1994
Start of on-site construction for building/structures demolition and decontamination (1st phase of site Remedial Action and date that triggers a five-year review).	9/12/1995
Completion of on-site construction for building/structures demolition and decontamination	12/28/1995
ESD issued by EPA, primarily changing soil and sediment stabilization from "in-situ" to "ex-situ", and changing cap design	11/26/1996
PRP Remedial Design approved by EPA	3/5/1997
Start of on-site construction for stabilization remedy (2nd phase of site Remedial Action)	3/11/1997
Pre-final inspection of Phase II remedial action	11/19/1997
Preliminary Close Out Report signed	8/28/1998
O & M Plan approved by EPA	9/18/1998

III. Background

Physical Characteristics

The Acme Site property includes a four-acre facility located on Canal Street adjacent to and upgradient of the Green River in Riverside, Massachusetts. Riverside is a community of approximately 12,000 residents, located in Waters County. In addition to the facility, the site includes the adjacent wetlands, wooded area, and the immediately adjacent portion of the river. The facility is located 200 feet northeast of the Green River and is within the river's 100-year flood zone. The site is bordered by Canal Street, wetlands and woodlands, the Green River, and a soccer field. Residential and commercial properties are located across Canal Street from the site (See Attachment 1).

Land and Resource Use

The historic land use of the site has involved some petroleum- or solvent-related industry since at least 1900. From at least 1974 until operations ceased in 1978, activities at the site included waste oil and solvent recovery and disposal. Since 1978, the facility has been inactive.

The current land use for the surrounding area is residential, commercial and recreational (the adjacent soccer field). The Green River is used for swimming and fishing. Although there have been a number of zoning changes over the years, it is anticipated that a mix of land uses similar to that described will continue into the future. In establishing cleanup requirements for the site, EPA considered the theoretical possibility of residential development at the site. The site itself is currently fenced and the treated, stabilized soils and sediments are contained within the fenced area under an impermeable cap.

The groundwater aquifer underlying the site is currently not used as a drinking water source. The dominant groundwater flow direction is to the southwest toward the Green River.

History of Contamination

The Acme facility reclaimed used oils and solvents from State collection points, treated them with a heat process, and sold them as lube oil and heavy fuel mixtures. In the course of these operations, spills occurred causing contamination of soils, sediments, and groundwater. Contamination in groundwater at the site consists primarily of volatile organic compounds (VOCs), including benzene and methylene chloride. Contaminants in soils and sediments include polychlorinated biphenyls (PCBs), polyaromatic hydrocarbons (PAHs), VOCs, and other organics and lead. Contamination at the site was discovered in the course of several property inspections conducted by the State which documented improper maintenance, as well as waste oil and hazardous materials spills. Millions of gallons of waste were left behind in tanks and lagoons when the owner abandoned the facility in 1978.

Initial Response

From 1978 to 1984, as a result of State enforcement efforts, approximately 1.5 million gallons of waste material were removed from the site during a number of separate events. In 1982, the State requested assistance from EPA's Superfund program. EPA discovered several leaking tanks and contaminated ditches, as well as saturated soils. The site was proposed for the National Priorities List

(NPL) on December 30, 1982, and finalized on the NPL in March 1983. In 1986, interim measures were taken to establish complete fencing of the site, demolish and dispose of 19 storage tanks, dispose of the oil and water contained in the tanks, and dispose of sludge generated during the cleaning of tanks. In January 1992, the Remedial Investigation/Feasibility Study was made available to the public. In March 1992, the Proposal Plan identifying EPA's preferred remedy was presented to the public, starting the period for public comment.

Basis for Taking Action

Contaminants

Hazardous substances that have been released at the site in each media include:

Soil

PCBs
PAHs
1,1-Dichloroethane
Cis-1,2-Dichloroethylene
Trans-1,2-Dichloroethylene
1,1,1-Trichlorethane
Trichloroethylene
Tetrachloroethylene
Benzene
Lead

Groundwater

Bis (2-ethylhexyl) Phthalate
Vinyl Chloride
1,1-Dichloroethane
Cis-1,2-Dichloroethylene
Trans-1,2-Dichloroethylene
1,1,1-Trichlorethane
Methylene Chloride
Trichloroethylene
Tetrachloroethylene
Benzene
2-Butanone (MEK)
Acetone
Lead

Lagoon Sediment

Bis (2-ethylhexyl) Phthalate
PAHs
1,1-Dichlorethane
1,1,1-Trichloroethane
Trichloroethylene
Tetrachloroethylene
Methylene Chloride
Benzene
Acetone
Lead

Wetland Sediment

PCBs
PAHs
Arsenic
Lead
Zinc

Exposures to soil, groundwater, wetland sediment, and lagoon sediment are associated with significant human health risks, due to exceedance of EPA's risk management criteria for either the average or the reasonable maximum exposure scenarios. The carcinogenic risks were highest for exposures to lagoon sediments due to the high concentrations of carcinogenic polyaromatic hydrocarbons (PAHs). Non-

carcinogenic hazards were highest for exposure to wetland sediment due to the high concentrations of lead detected in the medium. Risks from exposure to soil were significant due to the presence of TCE, PCE, and PCBs. Potential risks associated with exposure to groundwater are attributed to the presence of a variety of VOC contaminants that exist at concentrations that exceed State and Federal MCLs.

IV. Remedial Actions

Remedy Selection

The ROD for the Acme Site was signed on September 30, 1992. Remedial Action Objectives (RAOs) were developed as a result of data collected during the Remedial Investigation to aid in the development and screening of remedial alternatives to be considered for the ROD. The RAOs for Acme were divided into the following groups:

Source Control Response Objectives

- Minimize the migration of contaminants from the property soils and lagoon sediment that could degrade groundwater quality;
- Reduce risks to human health by preventing direct contact with, and ingestion of, contaminants in the property soils, wetland sediments, and lagoon sediments, and by preventing potential ingestion of contaminated groundwater;
- Reduce risks to the environment by preventing direct contact with, and ingestion of, contaminants in the wetland sediments; and
- Minimize the migration of contaminants (*i.e.*, from property soils, lagoon sediments, and wetland sediments) that could result in surface water concentrations in excess of Ambient Water Quality Criteria.

Management of Migration Response Objectives

- Eliminate or minimize the threat posed to human health and the environment by preventing exposure to groundwater contaminants;
- Prevent further migration of groundwater contamination beyond its current extent; and
- Restore contaminated groundwater to Federal and State applicable or relevant and appropriate requirements (ARARs), including drinking water standards, and to a level that is protective of human health and the environment within a reasonable period of time.

The major components of the source control remedy selected in the ROD include the following:

1. Decontamination, demolition, and off-site disposal of property structures; treatment and discharge of lagoon surface water;
2. Consolidation of contaminated property soils with lagoon and wetland sediments on site property;
3. In-situ mixing and stabilization of property soils/sediments with treatment agents to bind

contaminants into a stable matrix;
4. Construction of a permeable cap over stabilized property soils and sediments, and grading and planting of the cap's surface;
5. Restoration of wetlands;
6. Implementation of institutional controls on groundwater use and land development; and
7. Long-term monitoring of groundwater, wetland sediments, and Green River water and sediments.

The major components of the management of migration remedy selected in the ROD include:

1. Use of monitored natural attenuation (MNA) to achieve groundwater cleanup levels;
2. Groundwater monitoring of existing wells on the Acme property and of monitoring wells adjacent to the property;
3. Sediment sampling of portions of the wetland and the Green River, and where groundwater discharges to the wetland and the Green River;
4. Surface water sampling in areas adjacent to the wetland and in the Green River; and
5. Five-year site reviews to assess site conditions, contaminant distributions, and any associated site hazards.

An ESD was issued on November 26, 1996. Subsurface conditions including the existence of building foundations and low soil workability rendered in-situ stabilization impracticable. Additionally, Potentially Responsible Parties (PRPs) suggested adding a geosynthetic layer to the cap that would make it an impermeable cap rather than a soil cap. EPA approved the recommended change. The primary changes documented in the ESD were:

- Ex-situ stabilization instead of in-situ; and
- Construction of an impermeable cap instead of a permeable cap.

The change to ex-situ stabilization led to the necessity of designating a Corrective Action Management Unit (CAMU) at the site concurrent with the ESD. This designation allowed the handling and temporary storage of contaminated soils and sediments.

Institutional controls are required for the Acme property as well as for the adjacent Town-owned property, the only properties on or near the site requiring institutional controls. These institutional controls are established through the Access and Institutional Controls Agreement between the Performing Settling Defendants (PSDs) and the Town of Riverside, dated October 20, 1994, and recorded on June 19, 1997 in the Waters County Registry of Deeds.

Remedy Implementation

In a Consent Decree (CD) signed with EPA on September 18, 1994, 112 PSDs agreed to perform the remedial design/remedial action (RD/RA) and pay past costs for cleaning up the site. The Remedial Design (RD) was conducted in conformance with the ROD as modified by the ESD. The RD was approved by EPA on March 5, 1997.

The Remedial Action (RA) took place in two phases. The first phase entailed the decontamination, demolition and off-site disposal at a non-hazardous waste landfill of property structures. The activities for this phase were initiated on September 12, 1995 and were completed on December 28, 1995. The major

components of this phase of the RA were the following:

- Decontamination of the buildings and structures on the property;
- Removal, treatment, and discharge to the Green River of water from the basement of one building and water collected from decontamination;
- Collection and analyses of composite samples of buildings and structures;
- Demolition and off-site disposal as non-hazardous waste of property buildings and structures and off-site disposal of miscellaneous debris from the property;
- Removal and off-site disposal of two underground storage tanks and their contents; and
- Restoration of demolition areas to match existing grade.

The second phase entailed all other remedial activities. Components 2 through 7 of the Source Control Remedy constituted the primary activities performed as the second phase of the RA. The activities for the second phase of the RA were formally initiated on March 11, 1997 when the PSDs awarded the RA contract. The contractor conducted remedial activities as planned and EPA and the State conducted a pre-final inspection on November 19, 1997. During this period, 1,606 cubic yards of lagoon sediment, 1,187 cubic yards of wetland sediment, and 8,000 cubic yards of soil were treated, stabilized, and placed under the impermeable cap. In addition, a fence with warning signs and surface water drainage structures were built. At this time, the preparation for the wetland restoration (grading and backfilling of clean sediment material) and the planting of new replacement wetland species was accomplished. The pre-final inspection concluded that construction had been completed in accordance with the remedial design plans and specifications and did not result in the development of a punch list.

The site achieved construction completion status when the Preliminary Close Out Report was signed on August 28, 1998.

EPA and the State have determined that all RA construction activities, including the implementation of institutional controls, were performed according to specifications. It is expected that cleanup levels for all groundwater contaminants will have been reached within approximately ten years. After groundwater cleanup levels have been met, EPA will issue a Final Close Out Report.

System Operation/Operation and Maintenance

The PSDs are conducting long-term monitoring and maintenance activities according to the operation and maintenance (O&M) plan that was approved by EPA on September 8, 1998. The primary activities associated with O&M include the following:

- Visual inspection of the cap with regard to vegetative cover, settlement, stability, and any need for corrective action. In addition, the cap is scheduled to be mowed semi-annually;
- Inspection of the drainage swale for blockage, erosion and instability, and any need for corrective action;

- Inspection of the condition of groundwater monitoring wells;
- Environmental monitoring: Quarterly monitoring of groundwater, wetland surface water and sediment, and Green River surface water and sediment; and
- Engineered wetlands inspection and assessment: Inspections are conducted primarily for the purposes of assessing both weed control needs and the survival of plantings. Assessments are performed specifically to determine if the engineered wetlands are meeting the performance standards regarding the survival and density of desired wetland species.

The primary cleanup of the Acme Site took place during the construction phase of the Remedial Action (*i.e.* the stabilization of contaminated soil and sediments). The other remaining component of cleanup is the natural attenuation of groundwater, as the source of groundwater contamination in soil and sediment has been removed. Therefore, as indicated in the planned elements above, the primary O&M activities have been geared towards monitoring groundwater, surface water, sediments, wetlands, inspections, and maintenance of the cap.

A currently evolving issue exists with regard to the engineered wetlands. The total area of engineered wetlands at the Acme Site is 0.7 acres. This area encompasses wetland habitats that were replanted with appropriate wetland plant species following the removal of contaminated sediments during the RA. As previously mentioned, there are performance standards with regard to density of desired plant species and to minimization of weeds and other undesirable species. The PSDs are obligated to meet these standards. During the course of the O&M period, there have been repeated access issues involving the property abutting the southern border of the Acme property. During the RA, contaminated sediments were removed from this property, clean sediment was backfilled, and wetland plants were planted. Since completion of the RA, the owner of this property has prevented PSD contractors from performing maintenance (weeding and replanting, as necessary) in an area that is highly at risk from invasive species. The area affected by this issue is 0.32 acres. EPA, the Riverside Conservation Commission, and the PSDs are working together to determine if there is additional wetland acreage at the site which may be amenable to restoration or enhancement. If an appropriate area is found, it may be substituted for the 0.32 acre area that is not accessible for maintenance. The failure to provide proper maintenance for the wetlands does not impact the protectiveness of the site.

O&M costs include cap and drainage structure maintenance, sampling and monitoring efforts, monitoring well maintenance, and wetlands maintenance. In the first year, costs were higher due to an extra effort required to establish the vegetative cover on the cap and to establish wetlands. Less effort was required the second year and the PSDs were denied access by a property owner and were not able to maintain all of the wetlands. Costs are expected to rise when additional wetlands are identified and developed. The O&M costs for the first two years are consistent with the originally estimated annual costs of $20,000 per year.

Table 2 - Annual System Operations/O&M Costs

Dates		Total Cost rounded to nearest $1,000
From	To	
9/1998	9/1999	$22,000.00
9/1999	9/2000	$17,000.00

V. Progress Since the Last Five-Year Review

This was the first five-year review for the site.

VI. Five-Year Review Process

Administrative Components

Members of the PSDs and the MADEP were notified of the initiation of the five-year review on February 1, 2000. The Acme Five-Year Review team was led by Mary Jones of EPA, Remedial Project Manager (RPM) for the Acme Site, and included members from the Regional Technical Advisory staff with expertise in hydrology, biology, and risk assessment. Tom McDuff of the State assisted in the review as the representative for the support agency.

From March 1 to March 15, 2000, the review team established the review schedule whose components included:

- Community Involvement;
- Document Review;
- Data Review;
- Site Inspection;
- Local Interviews; and
- Five-Year Review Report Development and Review.

The schedule extended through August 31, 2000.

Community Involvement

Activities to involve the community in the five-year review were initiated with a meeting in early January 2000 between the RPM and the Community Involvement Coordinator (CIC) for the Acme Superfund site. A notice was sent to two local newspapers that a five-year review was to be conducted and that there would be a public meeting on April 20, 2000. A letter stating the same was sent to the Community Advisory Group (CAG), the Waters County Department of Health, the Fire and Rescue Department of Riverside, the County Commissioner's office, and the residents of properties adjacent to the Acme Superfund site. The letter invited the recipients to submit any comments to EPA.

During the public meeting, representatives of the CAG and local residents expressed concerns that work be completed as soon as possible at the site as they were concerned about the stigma that may be

attached to the property in the future, limiting its availability for redevelopment. None of the attendees expressed any concerns over the protectiveness of the remedy.

On September 11, 2000, a notice was sent to the same local newspapers that announced that the Five-Year Review report for the Acme Superfund site was complete, and that the results of the review and the report were available to the public at the Riverside Town Library and the EPA Region 1 office.

Document Review

This five-year review consisted of a review of relevant documents including O&M records and monitoring data (See Attachment 3). Applicable groundwater cleanup standards, as listed in the 1992 Record of Decision, were reviewed (See Attachment 4).

Data Review

Groundwater Monitoring

Groundwater monitoring has been conducted at the Acme Site since the late 1980s. In general, most contaminants were detected at their highest levels early in the Removal/Remedial history of the site (1989 to 1990). This high level followed by a drop in contaminant levels may well have been the result of removal activities eliminating significant source material.

The evaluation of the natural attenuation processes at the site was achieved by evaluating four indicators that are recommended in the *Use of Monitored Natural Attenuation at Superfund, RCRA Corrective Action, and Underground Storage Tank Sites* (OSWER Directive No. 9200.4-17P, April 21, 1999) for evaluating the performance of an MNA remedy. The four indicators are:

- Demonstrate that natural attenuation is occurring according to expectations;
- Detect changes in environmental conditions that may reduce the efficacy of the natural attenuation processes;
- Identify any potentially toxic or mobile transformation products; and
- Verify that the plume is not expanding either downgradient, laterally, or vertically.

Since construction completion in 1997, 8 of the 13 contaminants for which groundwater cleanup levels have been established, remained below their respective cleanup goals in all sampling events. Furthermore, for the five contaminants that have exceeded their cleanup goals in recent sampling events, there is a marked trend downward in concentrations. Recent monitoring results for the five contaminants are shown in Table 3. MW-104b, MW-104c, and MW-105b are located on the southern end of the treatment area which is the downgradient side. Therefore, trends in contaminant levels in these wells are good indicators of the fate of contaminants remaining in the groundwater near to the original source areas. In MW-104b and MW-104c, there is a clear downward trend in benzene concentrations, although concentrations remain above the cleanup goals. There is a clear indication that concentrations of TCE and the daughter products, cis 1,2-DCE and vinyl chloride are trending downward in MW-105b and MW-104c. This monitoring record indicates that the groundwater attenuation process conceptualized in the ROD is proceeding essentially as expected.

Table 3 - Quarterly Comparison of Groundwater Concentrations

Contaminant	Well No.	MCL (ppb)	Concentration in ppb				
			3/1999	6/1999	9/1999	12/1999	3/2000
Benzene	104b	5	110*	130*	310 (est)*	120*	58*
Benzene	104c	5	2,300*	4,900*	530*	190*	39*
Benzene	103c	5	100*	130*	130*	100*	NS
Trichlorethene	105b	5	15 (est)*	5.5*	ND	0.29 (est)	0.014 (est)
Vinyl chloride	105b	2	13*	5.2*	ND	ND	5.9 (est)*
cis-1,2,-Dicloroethene	104c	70	ND	78*	7.4 (est)	5.8	0.88
Lead	104c	0.015	0.005 (est)	0.004 (est)	0.017*	ND	0.003 (est)

* = Exceeds Cleanup Level
(est) = Estimated Value
ND = Not Detected
NS = Not Sampled

No monitoring of environmental conditions that may affect the efficacy of the MNA remedy is being conducted at this time. Given that contaminant concentrations continue to decline, such monitoring may not be necessary, as attenuation processes appear to be functioning as expected.

No potentially toxic or mobile transformation products have been identified during sampling events that were not already present at the time of the ROD, and therefore have cleanup goals specified in the ROD.

Regarding plume migration, there is some concern that the plume may be migrating downgradient toward the Green River. Concentrations of benzene in MW-103c have remained relatively stable since March 1999, lacking the downward trend in concentrations for this contaminant seen in other wells. This well is located downgradient from the treatment area and is closest to the river. This may be an indication that the plume is being pulled toward the river. The lack of a sampling point for the March 2000 event, due to the area of the well being flooded, gives rise to further concern. In the future, if it is not possible to obtain a sample during a scheduled monitoring event, provisions have been made to return to the site at a later date to obtain the sample and ensure that the monitoring record is complete.

Surface Water and Sediment Monitoring

Quarterly analysis of surface water samples taken in areas adjacent to the wetland and in the Green River found that all levels of contaminants of concern were below detection. Analysis of sediment samples taken in portions of the wetland and the Green River where groundwater discharges to the surface found contaminant levels also below detection limits.

Site Inspection

Inspections at the site were conducted on March 12, and May 23, 2000, by the RPM and an EPA biologist (See Attachment 5). The purpose of the inspections was to assess the protectiveness of the remedy, including the presence of fencing to restrict access, the integrity of the cap and the condition of the restored wetlands. Institutional controls were evaluated by visiting the County Planning Office to review zoning maps and by visiting the County Department of Health to review information on the site. A visit to the County Office of Public Records to review the property deed confirmed that a deed covenant had been filed.

No significant issues have been identified at any time regarding the cap, the drainage structures, or the fence. Examination of the cap revealed that there had been some slight burrowing of small animals. Another minor issue was trespassing and its effect on plantings within restored wetlands. As noted, a joint effort between the governments and the PSDs is being made to potentially change some of the wetland areas which are subject to restoration. In addition, the use of additional fencing is being considered within the site property boundaries to inhibit trespassing and better protect restored wetland plantings.

The institutional controls that are in place include prohibitions on the use or disturbance of groundwater until cleanup levels are achieved, excavation activities, disturbance of the cap, and any other activities or actions that might interfere with the implemented remedy. No activities were observed that would have violated the institutional controls. The cap and the surrounding area were undisturbed, and no new uses of groundwater were observed.

Interviews

Interviews were conducted with various parties connected to the site. Marjorie Edwards, owner of nearby Pliny Products, was interviewed on June 17, 2000. Two nearby residents, Alice Parsons and Michael Smith, were interviewed on July 18, 2000. No significant problems regarding the site were identified during the interviews. However, Mr. Smith and Ms. Parsons did note that occasional passers by have walked through the site. Paul Wainwright, a representative of the Riverside Conservation Commission, was interviewed on July 18, 2000, and expressed concern that requirements for wetland mitigation were not being observed. Mr. Wainwright was, however, confident that the problem would be resolved when a parcel of neighboring land would be selected for the establishment of new wetlands. During the May inspection, EPA interviewed the staff of the Fire and Rescue Department of Riverside, MA. None of the staff were able to identify any concerns regarding the site and there had not been any emergency responses at the site since the end of remedial construction.

VII. Technical Assessment

Question A: Is the remedy functioning as intended by the decision documents?

The review of documents, ARARs, risk assumptions, and the results of the site inspection indicates that the remedy is functioning as intended by the ROD, as modified by the ESD. The stabilization and capping of contaminated soils and sediments has achieved the remedial objectives to minimize the migration of contaminants to groundwater and surface water and prevent direct contact with, or ingestion

of, contaminants in soil and sediments. The effective implementation of institutional controls has prevented exposure to, or ingestion of, contaminated groundwater.

Operation and maintenance of the cap and drainage structures has, on the whole, been effective. A few small areas showed evidence of burrowing of small animals. The burrows did not penetrate beyond the soil layer, and so did not affect protectiveness. The PSDs were arranging for filling of the burrows and will include the task of inspection and repair of small animal burrows in future O&M routines. O&M annual costs are consistent with original estimates and there are no indications of any difficulties with the remedy.

Where the PSDs have had access to wetlands, the maintenance of the wetlands has been good. A 0.32-acre portion of the wetlands has not been maintained because the property owner where the wetlands are located has denied access to the PSDs. EPA, the Riverside Conservation Commission, and the PSDs are currently working to identify an alternate location where wetlands can be developed. The failure to meet the wetlands mitigation requirements for the site does not affect the potential for release of contaminants and does not affect protectiveness for the site.

There were no opportunities for system optimization observed during this review. The monitoring well network provides sufficient data to assess the progress of natural attenuation within the plume, and maintenance on the cap is sufficient to maintain it's integrity. There is some concern that the plume may be migrating downgradient toward the Green River. Concentrations of benzene in MW-103c have remained relatively stable since March 1999, lacking the downward trend in concentrations for this contaminant seen in other wells. This well is located downgradient from the treatment area and is closest to the river. This may be an indication that the plume is being pulled toward the river. The lack of a sampling point for the March 2000 event, due to the area of the well being flooded, gives rise to further concern.

The institutional controls that are in place include prohibitions on the use or disturbance of groundwater until cleanup levels are achieved, and prohibitions on excavation activities, disturbance of the cap, and any other activities or actions that might interfere with the implemented remedy. No activities were observed that would have violated the institutional controls. The cap and the surrounding area were undisturbed, and no new uses of groundwater were observed. The fence around the site is intact and in good repair.

Question B: Are the exposure assumptions, toxicity data, cleanup levels, and remedial action objectives (RAOs) used at the time of the remedy selection still valid?

There have been no changes in the physical conditions of the site that would affect the protectiveness of the remedy.

Changes in Standards and To Be Considereds

As the remedial work has been completed, most ARARs for soil contamination cited in the ROD have been met. ARARs that still must be met at this time and that have been evaluated include: the Safe Drinking Water Act (SDWA) (40 CFR 141.11-141.16) from which many of the groundwater cleanup levels were derived - [Maximum Contaminant Levels (MCLs), and MCL Goals (MCLGs)]; ARARs related

to wetland protection; and ARARs related to post-closure monitoring. A list of ARARs is included in Attachment 3. There have been no changes in these ARARs and no new standards or TBCs affecting the protectiveness of the remedy.

Changes in Exposure Pathways, Toxicity, and Other Contaminant Characteristics

The exposure assumptions used to develop the Human Health Risk Assessment included both current exposures (older child trespasser, adult trespasser) and potential future exposures (young and older future child resident, future adult resident and future adult worker). There have been no changes in the toxicity factors for the contaminants of concern that were used in the baseline risk assessment. These assumptions are considered to be conservative and reasonable in evaluating risk and developing risk-based cleanup levels. No change to these assumptions, or the cleanup levels developed from them is warranted. There has been no change to the standardized risk assessment methodology that could affect the protectiveness of the remedy. The remedy is progressing as expected and it is expected that all groundwater cleanup levels will be met within approximately 10 years.

Question C: Has any other information come to light that could call into question the protectiveness of the remedy?

No ecological targets were identified during the baseline risk assessment and none were identified during the five-year review, and therefore monitoring of ecological targets is not necessary. All sediment and surface water samples analyzed found no contamination of wetlands or surface water. No weather-related events have affected the protectiveness of the remedy. There is no other information that calls into question the protectiveness of the remedy.

Technical Assessment Summary

According to the data reviewed, the site inspection, and the interviews, the remedy is functioning as intended by the ROD, as modified by the ESD. There have been no changes in the physical conditions of the site that would affect the protectiveness of the remedy. Most ARARs for soil contamination cited in the ROD have been met. There has been no changes in the toxicity factors for the contaminants of concern that were used in the baseline risk assessment, and there have been no change to the standardized risk assessment methodology that could affect the protectiveness of the remedy. There is no other information that calls into question the protectiveness of the remedy.

VIII. Issues

Table 4 - Issues

Issue	Currently Affects Protectiveness (Y/N)	Affects Future Protectiveness (Y/N)
Evidence of small animal burrows at a few locations on the southwest corner of the cap.	N	N

Issue	Currently Affects Protectiveness (Y/N)	Affects Future Protectiveness (Y/N)
Failure to maintain 0.32 acres of the total 0.7 acres of wetlands constructed to comply with wetlands mitigation requirements for the site.	N	N
Inadequate monitoring data to verify that the plume is not migrating	N	Y

IX. Recommendations and Follow-Up Actions

Table 5 - Recommendations and Follow-Up Actions

Issue	Recommendations/ Follow-up Actions	Party Responsible	Oversight Agency	Milestone Date	Affects Protectiveness? (Y/N)	
					Current	Future
Animal burrows in cap	Repair current burrows; establish O&M task to ensure future burrows are identified and repaired	PSDs	State/EPA	6/30/2001	N	N
0.32 acres of wetlands not maintained due to access problems	Identify alternate location at or near the site for wetlands development	PSD, Riverside Conservation Commission	State/EPA	9/30/2001	N	N
Inadequate monitoring data	1) Increase monitoring frequency for MW-103 cluster; 2) Investigate groundwater recharge to river; and 3) Sample sediments and groundwater flux at recharge points.	PSDs	State/EPA	9/30/2001	N	Y

X. Protectiveness Statement

The remedy is expected to be protective of human health and the environment upon attainment of groundwater cleanup goals, through natural attenuation, which is expected to require 10 years to achieve. In the interim, exposure pathways that could result in unacceptable risks are being controlled and institutional controls are preventing exposure to, or the ingestion of, contaminated groundwater. All threats at the site have been addressed through stabilization and capping of contaminated soil and sediments, the installation of fencing and warning signs, and the implementation of institutional controls.

Long-term protectiveness of the remedial action will be verified by obtaining additional groundwater samples to fully evaluate potential migration of the contaminant plume downgradient from the treatment area and towards the river. Current data indicate that the plume remains on site. Additional sampling and analysis will be completed within the next six months. Current monitoring data indicate that the remedy is functioning as required to achieve groundwater cleanup goals.

XI. Next Review

The next five-year review for the Acme Superfund Site is required by September 2005, five years from the date of this review.

Applicable or Relevant and Appropriate Requirements (ARARs)

Medium/ Authority	ARAR	Status	Requirement Synopsis	Action to be taken to Attain ARAR
Groundwater/ SDWA	Federal - SDWA - Maximum Contaminant Levels (MCLs) (40 CFR Part 141.11-141.16) and non-zero Maximum Contaminant Level Goals (MCLGs)	Relevant and Appropriate	Standards (MCLs) have been adopted as enforceable standards for public drinking water systems: goals (MCLGs) are non-enforceable levels for such systems.	Remediation of contaminated material in soils and sediment will eliminate ongoing discharges of contaminants to groundwater. MCLs and non-zero MCLGs will be attained in groundwater at the point of compliance.

Medium/ Authority	ARAR	Status	Requirement Synopsis	Action to be taken to Attain ARAR
Surface Water/CWA	Federal - CWA - Ambient Water Quality Criteria (AWQC)- Protection of Freshwater Aquatic Life, Human Health, Fish Consumption	Relevant and Appropriate	AWQC are developed under the Clean Water Act (CWA) as guidelines from which states develop water quality standards. CERCLA §121(d)(2) requires compliance with such guidelines when they are relevant and appropriate. A more stringent AWQC for aquatic life may be found relevant and appropriate rather than an MCL, when protection of aquatic organisms is being considered at a site. Federal AWQC are health-based criteria which have been developed for 95 carcinogenic compounds; these criteria consider exposure to chemicals from drinking water and/or fish consumption. Acute and chronic exposure levels are established.	The selected remedy will attain AWQC in the wetland surface waters and river water after completion of remedial activities.
Groundwater/ CWA	State Department of Environmental Protection (DEP) - Massachusetts Groundwater Quality Standards (314 CMR 6.00)	Applicable	State groundwater quality standards have been promulgated for a number of contaminants. When the state levels are more stringent than federal levels, the state levels will be used.	The selected remedy will attain State standards in the groundwater at the point of compliance after completion of remedial activities.

Medium/ Authority	ARAR	Status	Requirement Synopsis	Action to be taken to Attain ARAR
Groundwater/ SDWA	State - 310 CMR 22.06 Maximum Contaminant Levels for Inorganic Chemicals in Drinking Water	Relevant and Appropriate	Maximum contaminant levels are established for inorganic chemical contaminants under 310 CMR 22.06. All public water systems must comply with the levels of inorganic contaminants which are listed in Table 1 of 310 CMR 22.06.	The selected remedy will attain State MCLs for inorganics in the groundwater at the point of compliance.
Groundwater/ SDWA	State - 310 CMR 22.07 Maximum Organic Chemical Contaminant Levels in Drinking Water	Relevant and Appropriate	310 CMR 22.07 establishes maximum contaminant levels for selected chlorinated hydrocarbons, pesticides and herbicides.	The selected remedy will attain State MCLs for organic contaminants in the groundwater at the point of compliance.
Air/CAA	Federal - CAA - National Emissions Standards for Hazardous Air Pollutants (NESHAP) (40 CFR Part 61)	Applicable	NESHAP standards have been promulgated for two organic compounds present at the site, benzene and vinyl chloride.	Remediation technologies which emit air contaminants regulated under NESHAPs will attain the appropriate standard during operation.
Soil/ Sediments/ RCRA	Federal - Resource Conservation and Recovery Act (RCRA) - Criteria for Classification of Solid Waste Disposal and Practices (40 CFR Part 257)	Relevant and Appropriate	Solid wastes containing PCBs greater than 10 ppm must not be incorporated into the soil (or mixed with surface soil) applied to land used for food chain or pasture crop production.	Any debris, soil, or sediment which contains greater than 10 ppm PCBs will be excavated and stabilized. Institutional controls will prohibit the use of the site for agriculture.

Medium/ Authority	ARAR	Status	Requirement Synopsis	Action to be taken to Attain ARAR
Air/CAA	Federal - CAA - National Ambient Air Quality Standards (NAAQS) (40 CFR Part 50)	Applicable	NAAQS define levels of primary and secondary levels for six common air contaminants [sulfur dioxide, particulate matter (PM_{10}), carbon monoxide, ozone, nitrogen dioxide and lead].	The levels established for these six air contaminants will be used as target levels which may not be exceeded by air release from on-site activities.
Surface Water/CWA	State Operation and Maintenance and Pretreatment Standards for Wastewater Treatment Works and Indirect Discharge (314 CMR 12.00)	Applicable	Regulations to ensure proper operation and maintenance of wastewater treatment facilities and sewer systems within the State.	Remedial activities will comply with all provisions of this regulation.
Air/OSHA	Federal - Occupational Health and Safety Act (OSHA) (29 CFR Part 1910.1000 - Air Contaminants)	To be Considered	Acceptable employee exposure levels have been promulgated for an extensive list of materials to control air quality in workplace environments.	Action levels for volatile and semi-volatile air contaminants will be established for implementation during on-site remedial actions. Exposure levels will also be used in the risk assessment to determine overall site risk.

Medium/ Authority	ARAR	Status	Requirement Synopsis	Action to be taken to Attain ARAR
Groundwater/ CWA	Federal - (Guidance) Groundwater Classification Guidelines	To be Considered	Classifies groundwater by its potential beneficial uses such as special groundwater (Class 1) which is "highly vulnerable to contamination because of the hydrological characteristics of the areas in which it occurs and characterized by either of the following factors: – The groundwater is irreplaceable; no reasonable alternative source of drinking water is available to substantial populations. – The groundwater is ecologically vital; the aquifer provides the base flow for a particularly sensitive ecological system that, if polluted, would destroy a unique habitat. Class 2 groundwater is classified as a current and potential source of drinking water and waters having other beneficial uses. All groundwater which does not fit under Class 1 and which is not heavily saline (total dissolved solids (TDS) > 10,000 mg/l) are considered Class 2 groundwater.	The groundwater aquifer will meet the standards under the SDWA for the appropriate classification of groundwater after completion of remedial activities.

Medium/ Authority	ARAR	Status	Requirement Synopsis	Action to be taken to Attain ARAR
Sediments/ CWA	Federal - NOAA Technical Memorandum NOS OMA 52	To be Considered	The memorandum identifies reference doses for various contaminants in sediments and their potential biological effects on biota exposed to the contaminants.	Contaminated sediments will be remediated.
Wetlands/ CWA	Federal - CWA Section 404(b)(1); 40 CFR Part 230, 33 CFR Parts 320 - 330	Applicable	Requirements under these codes prohibit the discharge of dredged or fill material into wetlands unless those actions comply with the substantive requirements which are identified under these regulations.	Discharges to wetlands around the site will comply with these requirements.
Wetlands/ CWA	Federal Executive Orders 11990 Protection of Wetlands	Applicable	Under this regulation, Federal agencies are required to minimize the destruction, loss, or degradation of wetlands, and preserve and enhance natural and beneficial values of wetlands.	Wetlands protection considerations will be incorporated into the planning and implementation of this selected remedy.

Medium/ Authority	ARAR	Status	Requirement Synopsis	Action to be taken to Attain ARAR
Floodplains/ RCRA	Federal 40 CFR Part 264.18 Location Standards	Relevant and Appropriate	This regulation identifies geological features that a proposed location for a RCRA hazardous waste treatment and/or disposal facility must avoid. Three specific geological features are identified of which two apply to the site. These features and the significance are: – Floodplain - A facility located in a 100-year floodplain must be designed, constructed, operated, and maintained to prevent washout of any hazardous waste unless the owner or operator can demonstrate to the EPA Regional Administrator that he can meet the criteria established under this subpart which exempts him from complying with this requirement.	This site is located within a 100-year floodplain and a portion of the site may be within 200 feet of a fault. On-site remediation activities will comply with the requirements of 40 CFR Parts 264.18(a) and (b).

Medium/ Authority	ARAR	Status	Requirement Synopsis	Action to be taken to Attain ARAR
Rivers/CWA	Federal - 16 USC 661 et. seq. Fish and Wildlife Coordination Act	Applicable	Mitigative actions must be taken to minimize potential adverse impacts to natural sources such as wetlands. Restoration of damaged natural features are required.	Relevant federal agencies will be contacted to help analyze impacts of the implementation of remedial alternatives on wildlife in wetlands and rivers. Restoration of impacted wetlands will occur once all excavation and stabilization activities are completed.
Wetlands/ CWA	State - Department of Environmental Protection - Wetlands Protection (310 CMR 10.00)	Applicable	These regulations are promulgated under Wetlands Protection Laws, which regulate dredging, filling, altering or polluting inland wetlands. Work within 100 feet of a wetland is regulated under this requirement. The requirement also defines wetlands based on vegetation types and requires that effects on wetlands be mitigated.	The selected remedy will include measures to mitigate and/or replace loss of habitat or hydraulic capacity in accordance with 310 CMR 10.00.

Appendix G
Methods and Examples for Evaluating Changes in Standards and Toxicity

[This page intentionally left blank.]

Methods and Examples for Evaluating Changes in Standards and Toxicity

This appendix provides a series of flowcharts and examples that you can use to aid in evaluating changes in promulgated standards and chemical toxicity characteristics. The following tables are arranged in two sets, with a generic decision flowchart first. A hypothetical example follows with an example of the flowchart filled in according to the information in the hypothetical example.

Exhibit G-1: Evaluating Changes in Standards

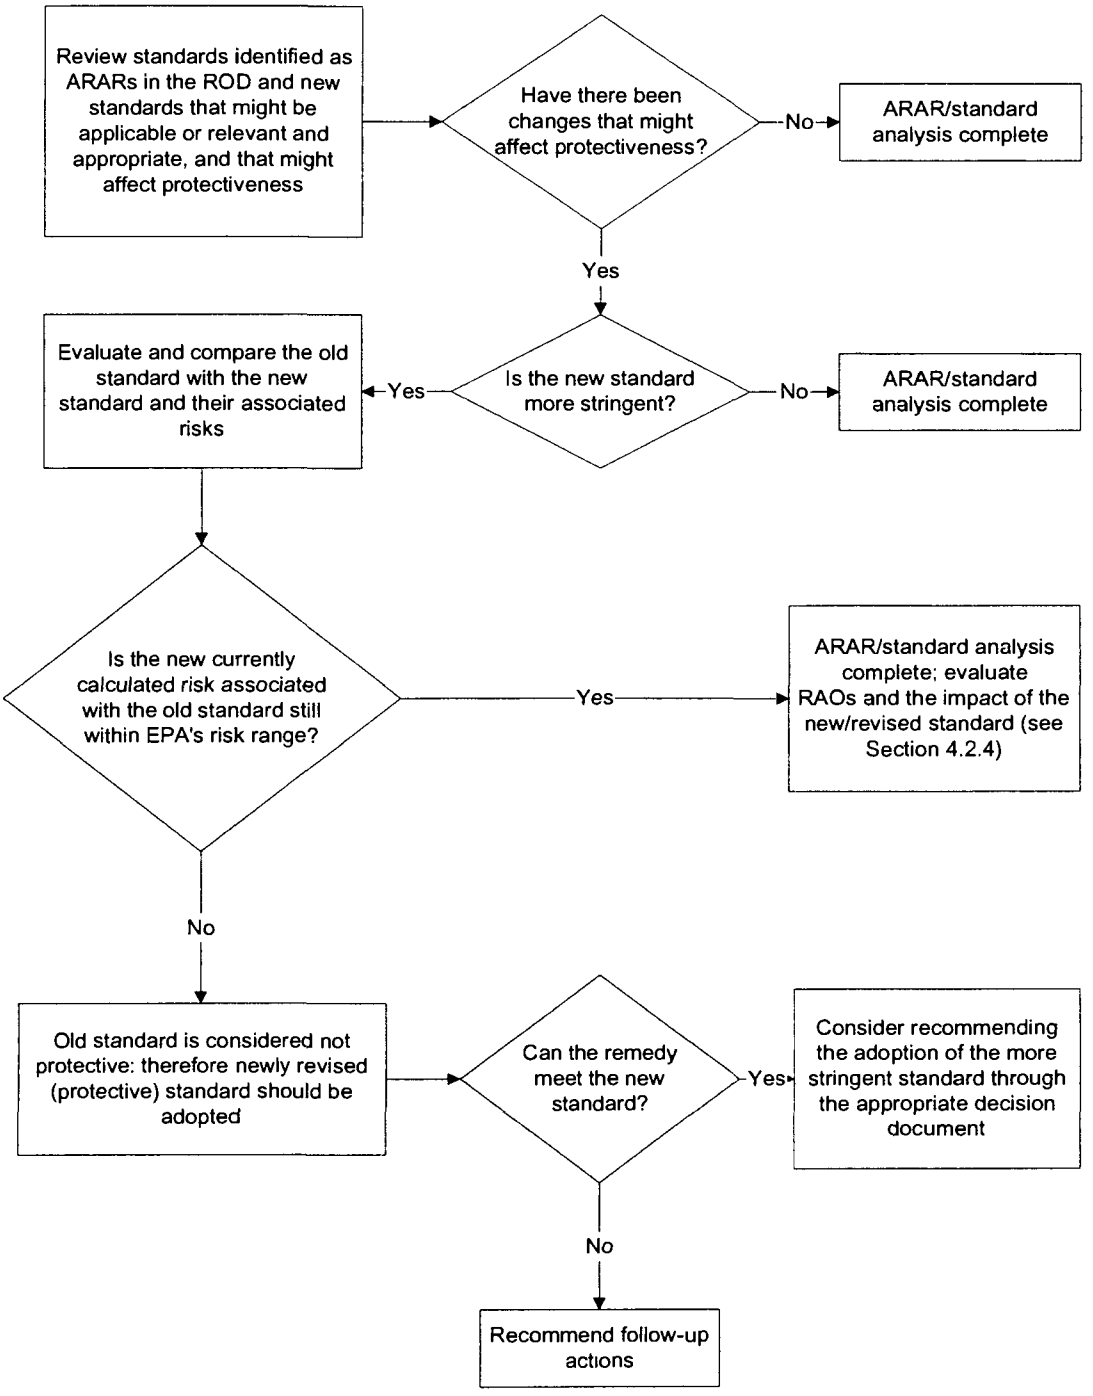

Exhibit G-2: Hypothetical Scenario for a Change in a Standard

During the 1998 Five-Year Review for the Flower Dye site in the State of Franklin, the review team learned that the State drinking water standard for 2,4-Dinitrochickenwire changed from 20 parts per billion (ppb) to 2 ppb. The Record of Decision (ROD), signed in 1988, identified the state standard for 2,4-Dinitrochickenwire as an ARAR and established a cleanup level for 2,4-Dinitrochickenwire at 20 ppb. The ROD also specified that the remedial action objective (RAO) for groundwater is to restore groundwater to drinking water standards. The remedy is to pump-and-treat groundwater using extraction and reinjection wells with air stripping.

In the ARAR/standard analysis (See Exhibit G-1) it was identified that the standard (ARAR) of 20 ppb at the time the ROD was signed had an associated risk of $5x10^{-5}$, which was within EPA's risk range. However, the current risk associated with the same level (20 ppb) now is $5x10^{-4}$ due to changes in the toxicity information that is the basis for the standard. This is generally considered outside of EPA's risk range and therefore, generally considered not protective. As part of the evaluation it was determined that the new standard (2 ppb) has an associated risk of $5x10^{-5}$, which is within EPA's risk range.

In examining the treatment records, monitoring reports, and existing groundwater modeling information, it was determined that the system can treat to 2 ppb, and potentially the remedy can achieve that level in the groundwater. Since the old standard (20 ppb) is no longer considered protective, further actions needed to be taken to ensure that the remedy achieves protectiveness. These actions included the adoption of a protective cleanup level. Therefore, the Five-Year Review report recommended that the new standard (2 ppb) be adopted through an Explanation of Significant Difference. The physical remedy did not have to be modified because it was determined that it could achieve the 2 ppb level. In addition, the RAOs would also be achieved and would not require any modification.

Exhibit G-3: Decision Process for a Hypothetical Change in Standard

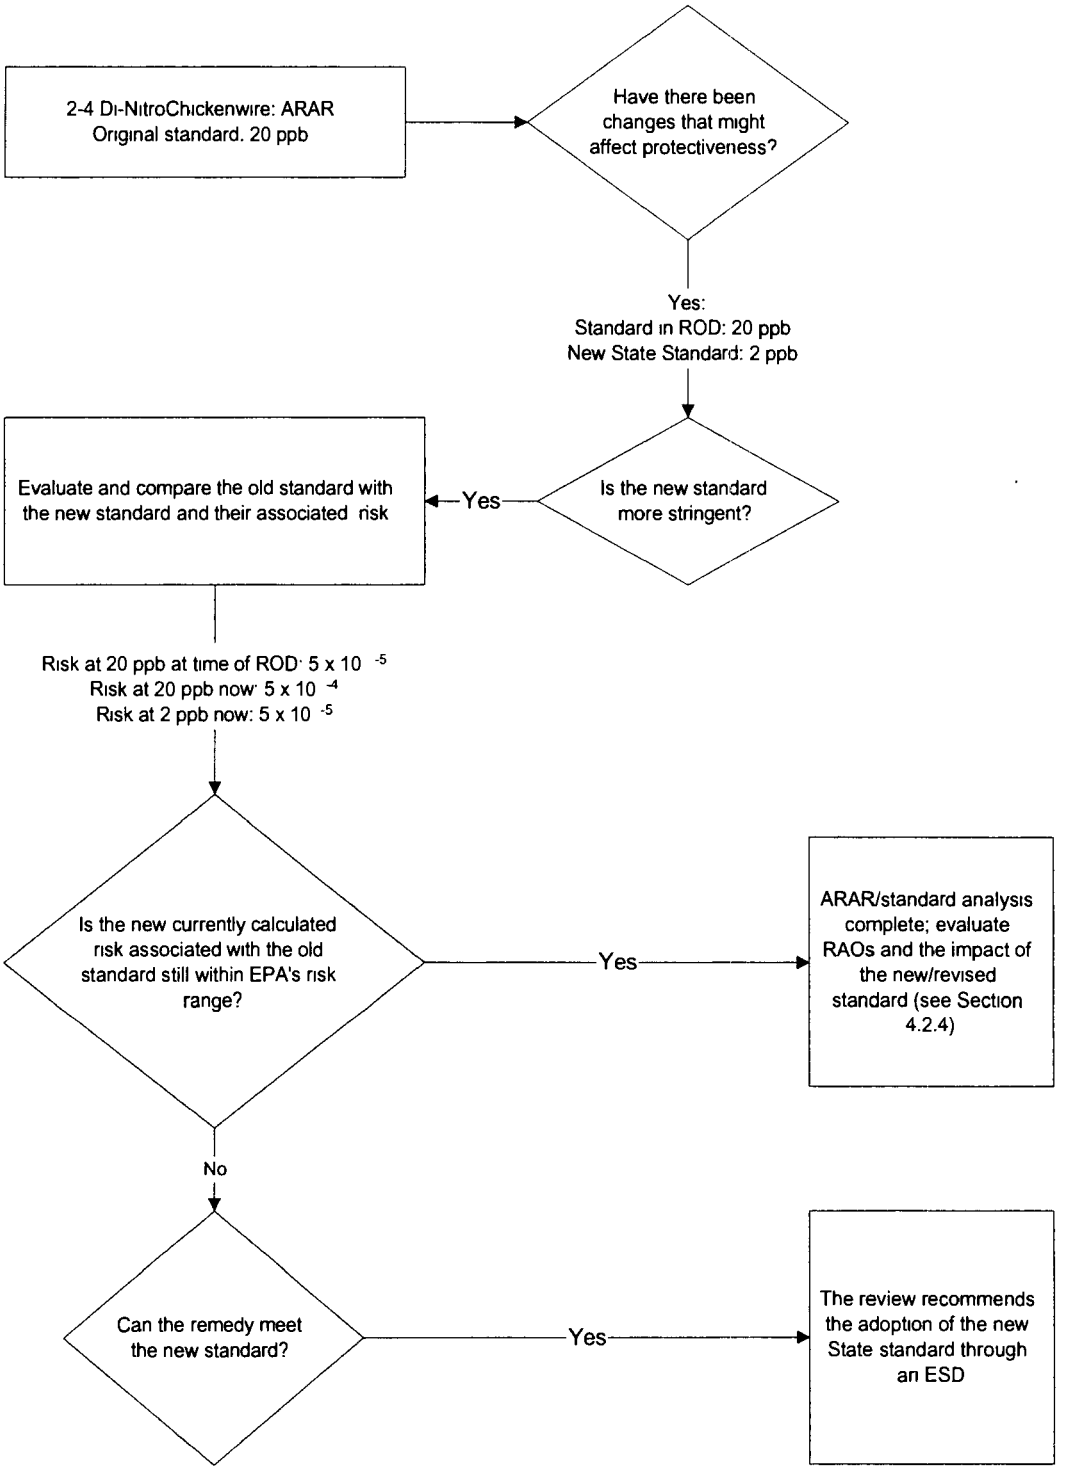

Exhibit G-4: Evaluating Changes in Toxicity and Other Contaminant Characteristics

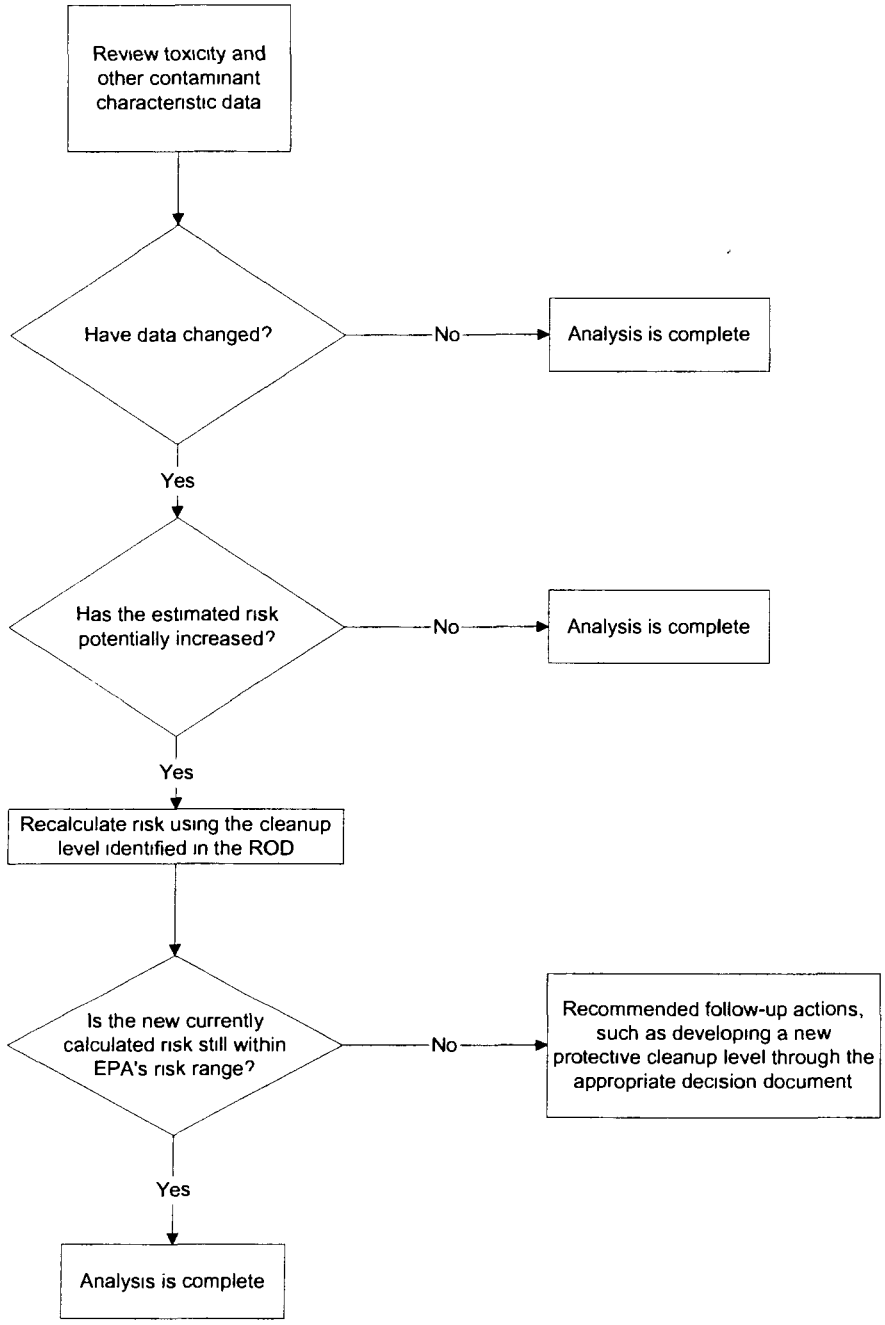

Exhibit G-5: Hypothetical Scenario for a Change in Toxicity

During the 1998 Five-Year Review at the Old Pesticide Disposal site in the State of Franklin, the review team determined that the Cancer Slope Factor (CSF) for the pesticide "Hypochem" had been increased in 1996 from 0.05 $(mg/kg\text{-}day)^{-1}$ to 20.00 $(mg/kg\text{-}day)^{-1}$. Hypochem, among other contaminants, had been found in the water supply well across the street from the Old Pesticide Disposal facility at a concentration of 0.001 mg/L. When the ROD was signed in 1986, this level was associated with a risk level less than one in one million excess cancer cases based on the following equations and site-specific exposure parameters:

$$\text{Average Daily Intake (mg/kg-day)} = (C_{Water} * IR*EF*ED)/(BW*AT) \quad (1)$$

where:

Parameter			Site Scenario
C_{Water}	=	Contaminant concentration in water (mg/L)	
IR	=	Drinking water intake (ingestion) rate (L/day)	2 L/day
EF	=	Exposure frequency (days/year)	350 days/year
ED	=	Exposure duration (years)	30 years
BW	=	Body weight (kg)	70 kg
AT	=	Average time (days)	25,550 days

$$\text{Target Risk (R)} = \text{Average Daily Intake} * \text{Cancer Slope Factor} \quad (2)$$

When equations (1) and (2) are combined, the allowable concentration of Hypochem (C_{Water}) that corresponds to a given risk level "R," can be determined by inserting the site-specific parameters into the following equation:

$$C_{water}\ (mg/L) = (R*BW*AT)\ /(CSF*IR*EF*ED) \quad (3)$$

The Old Pesticide Disposal site's original one in one million risk level R = $1x10^{-6}$) was based on the original CSF of 0.05. Thus, equation (3) yielded a health-based screening level for Hypochem of:

$$C_{Water} \text{ for R of } 1x10^{-6} = 0.001704 \text{ mg/L}$$

Since the actual concentration of Hypochem in the water in 1986 was 0.001 mg/L, and thus fell within acceptable limits, there was no need to reduce its levels. (The risk corresponded to 0.6 new cases per million people.) However, using the new CSF of 20.00 to achieve a one in one million risk level R = $1x10^{-6}$), the new health-based screening level for Hypochem becomes:

$$C_{Water} \text{ for R of } 1x10^{-6} = 0.00000426 \text{ mg/L}$$

and using the new CSF of 20.00 to achieve one in a ten thousand risk level R = $1x10^{-4}$), equation (3) yields a C_{Water} value of:

$$C_{Water} \text{ for R of } 1x10^{-4} = 0.000426 \text{ mg/L}$$

Exhibit G-5: Hypothetical Scenario for a Change in Toxicity, cont'd.

The 1986 ROD selected pumping and air stripping of the groundwater to remove solvents also found in the groundwater, and groundwater recharge. Based on sampling records of the recharge water, the stripping unit did not significantly reduce Hypochem concentrations. In fact the current concentration of Hypochem in groundwater is 0.0008 mg/L. Given the new cancer risk factor, the levels of Hypochem are not acceptable because the risk based on this new factor is greater than one in ten thousand (1×10^{-4}).

Based on this result, the Five-Year Review report recommended that a protective cleanup level be developed through the appropriate decision document. In addition, the physical remedy would have to be evaluated to determine whether the current system would be able to reduce the level of Hypochem to protective/acceptable concentrations.

Dredging up the truth

Records show GE was warned about health threats of PCBs decades before anti-dredging campaign

By Brendan J. Lyons

Updated 11:37 pm, Saturday, March 8, 2014

A view of the former GE plant near the Hudson River on March 25, 2014 in Hudson Falls, NY. (Paul Buckowski / Times Union) and empty barrels labeled General Electric insulating oil are seen at a dump site at South Glens Falls Drag strip on July 28, 1982. (Fred McKinney/Times Union archive)

CLICK HERE FOR DOCUMENTS, GRAPHICS AND MORE COVERAGE.

Fort Edward

For years, as it fought against being forced to clean up the Hudson River, General Electric Co. argued that an oil-like insulating fluid that had seeped into the river from its Washington County capacitor plants wasn't harmful to humans.

Besides, GE officials said, the river was cleaning itself.

Yet newly uncovered documents reveal that as early as the 1960s — decades before the government ordered GE to undertake the river dredging that is scheduled to resume this spring — company officials were warned of the potential serious health threats of polychlorinated biphenyls (PCBs), which their engineers described in confidential memos as "hazardous waste."

The documents also indicate that GE flushed far more PCBs into the river than government regulators have estimated, and that nearly a million pounds a year of additional PCBs were carted away by scavenger crews, dumped with an attitude characterized by a GE engineer in 1970 as "out of sight, out of mind."

While fighting a federally mandated cleanup, the longtime CEO of the company, Jack Welch, always insisted that PCBs are safe — a position he and GE hold to this day, despite scientific evidence to the contrary.

The records were obtained by the Times Union through a series of Freedom of Information Law requests at a critical time: GE has been battling several river communities over who will pay for alternate drinking-water supplies as the corporation mops up the PCB pollution that created a nearly 200-mile environmental disaster from Hudson Falls to the Atlantic Ocean — the nation's largest Superfund site.

The federally mandated dredging of the Upper Hudson is costing GE $1 billion. Taxpayers have spent hundreds of millions more in related cleanup costs, and there are growing calls for GE to participate in funding long-stalled dredging of the Champlain Canal, which also was tainted by PCBs from GE.

The documents raise an unsettling question: Did GE brush off its own employees' assessments of the risk of PCB pollution, later engaging in a lobbying and public relations campaign to change the public's perception of the dangers?

Such questions are reflections on history, rather than current reality, GE spokesmen say.

About this article

In August 2013, the Times Union's Brendan J. Lyons, a senior writer, and J. Robert Port, a former senior editor for investigations, began a months-long examination of General Electric Co.'s history of pollution in the Hudson River. Their efforts included interviewing current and former GE employees and reviewing thousands of documents from court cases, scientific studies and public records dating back more than 40 years. A series of Freedom of Information Law requests also gave the newspaper access to hundreds of GE's internal records, which were shared through pre-trial disclosures with attorneys for several communities along the upper Hudson River that sued GE in 2009 for contaminating their water supplies.

"The fact is GE acted diligently and responsibly in dealing with PCBs, complied with the law and regulations and has done an exceptional job on the dredging project," said Mark Behan, a GE spokesman.

Misleading the regulators

The Hudson River was dying.

In the fall of 1968, a cadre of environmental specialists from the state Health Department was touring the General Electric Co.'s capacitor plants in Hudson Falls and Fort Edward to learn more about industrial pollutants that were destroying the river's ecosystem. The federal Clean Water Act was still a few years away, but the state was studying the feasibility of a regional wastewater treatment facility, after decades of allowing GE and other companies to treat the embattled river like their own toxic landfill.

But as they took their tour, the state officials were being lied to about the level of heavy metals leaking into the river from GE's plants.

"We intensionally (sic) omitted some information ... which would have greatly compounded the problem in the eyes of the regulatory people; namely, the state Department of Health authorities," a GE engineer, Kenneth H. Harvey, wrote in an internal memo dated Sept. 21, 1968, a day after the meeting.

Jack Welch, who in 1981 became GE's CEO and one of the world's most celebrated business executives, scowled as he read Harvey's memo during a deposition last year in Palm Beach, Fla.

"This guy's ass should have been fired," Welch said. "The guy that got this memo should have had this guy in and understood what the hell he was doing and why he was doing it. That's not a practice of the General Electric Co. that I knew when I worked there."

The deposition by Welch, 78, his first testimony on GE's handling of PCBs, was never made public. The 300-page transcript and a video of the proceeding were obtained by the Times Union through FOIL requests that also gave the newspaper access to hundreds of internal GE records.

Welch's testimony, and that of numerous current or former GE officials, was compelled by a lawsuit filed against GE five years ago in federal court by the Saratoga County towns of Halfmoon, Stillwater and Waterford, the village of Stillwater, and the Saratoga County Water Authority. The municipal agencies have water systems tied to the Hudson River that they claim were tainted by the ongoing dredging project and the possibly millions of pounds of PCBs that were flushed into the river from GE's capacitor plants over a 30-year period.

The records reviewed by the Times Union include internal GE reports and correspondence on the company's knowledge and handling of PCBs. Despite the unprecedented insight, thousands of other internal company records remain shielded from public disclosure, including scores of documents related to GE's multimillion-dollar public relations campaign in opposition to dredging. GE has argued in federal court that those records are privileged — that is, not subject to disclosure — including communications with Behan, a public-relations strategist and former newspaper editor.

Last week Behan said GE and three of the plaintiffs in the case — the village and town of Stillwater and the town of Waterford — had reached a "settlement in principle." He declined to elaborate.

The case records show that GE began aggressively studying the health and environmental issues related to PCBs more than 40 years ago, and curtailed use in the early 1970s of what it suspected at the time was a more dangerous type of PCBs.

"Suspected carcinogens"

GE opened its Fort Edward manufacturing plant in 1946 and its Hudson Falls plant, a mile up the river, in 1951. For decades, the plants were a backbone of employment in the hardscrabble villages. But the payoff of jobs came with long-term environmental consequences.

According to court records, GE purchased an estimated 190 million pounds of PCBs over a period of decades, using it as a dielectric fluid to insulate its capacitors from overheating. PCBs, a coal-tar byproduct, were for many years the government's preferred chemical for that purpose, in part because they were effective at preventing fires while not interfering with conductivity.

But in 1979, amid growing evidence that PCBs may cause cancer and other serious health problems, they were banned by the U.S. Environmental Protection Agency.

Much of the Hudson River's pollution occurred when PCBs were spilled onto the ground and seeped into the bedrock below the factories. They were also flushed into the capacitor plants' wastewater systems, which poured into the nearby river.

GE officials have repeatedly insisted that the company never broke any environmental laws and its toxic discharges were "permitted." In fact, there was no government permitting system for most of the period that PCBs were in use. Legal opponents of GE assert that under the federal Refuse Act, hazardous discharges to a waterway were illegal, and that the company violated state and federal permits that were required beginning in the 1970s.

No one can accurately say how many pounds of PCBs ended up in the Hudson River or the bedrock under GE's capacitor plants. A GE spokesman said the company "has not issued an estimate of the volume of PCBs that were discharged to the river."

For more than a decade, the EPA has said 1.3 million pounds of PCBs entered the river, but even the EPA cannot say where that figure originated.

"That's one we've generally been using," said David King, director of the EPA's Hudson River field office in Fort Edward. "I wouldn't say it's irrelevant but it's nothing that can be quantified with any real accuracy."

GE's internal records suggest that the EPA's estimate falls far short.

Kenneth R. Murphy, an engineer who worked in GE's environmental pollution control division in Schenectady, wrote an analysis of the potential environmental damage in June 1970. His report came as other internal records show the company was becoming increasingly aware of the environmental dangers of PCBs. Murphy warned that controlling the company's PCB waste stream would be a "major undertaking" and estimated that GE annually discharged about 500,000 pounds of PCBs "directly to bodies of water."

"The Hudson River has been the major receiving stream," he wrote in his report, which was widely distributed inside the company but never made public.

Each year, an additional 900,000 pounds of PCB waste was being taken away by contractors — "scavengers who dispose of it in an 'out of sight, out of mind' manner," Murphy wrote. "Few, if any, scavengers give consideration to proper disposal of hazardous wastes," he added.

Murphy's report estimated that another 100,000 pounds of PCB-contaminated waste was sent each year to landfills, yet "there is no indication that any consideration was given to the handling of hazardous wastes in these landfills."

In a recent interview, Murphy, now 73 and living in Virginia, didn't back away from his 1970 report. But he cautioned that he used data "more from manufacturing people, some of them with limited education and not chemists or chemical engineers."

"I just compiled data that was given to me," said Murphy, who worked at GE for 23 years. "I think the company wanted to understand the size of the problem."

By the time Murphy's report was issued, the company was aware of the potential environmental risks of PCBs. A month earlier, GE had sent a letter to its utility customers warning that PCBs, which it referred to as "Pyranol," a GE trademark, were "a matter of growing concern as to their effect on some species of wildlife."

The May 1970 letter noted that Monsanto Company, which was the only U.S. manufacturer of PCBs and sounded the alarm on the concerns, "has been reviewing procedures to be sure that these materials do not find their way into land or water environment."

There are other records outlining GE's early concerns about PCBs. In October 1969, about eight months after a California newspaper reported on a "menacing new pollutant" causing problems for marine life and birds in San Francisco Bay, a product-safety engineer at GE's Schenectady headquarters wrote a memo documenting concerns about the ecological effects and toxic hazards of PCBs. The memo, sent to a high-ranking GE engineer, cited troubling reports by Monsanto and newspaper stories noting their "hormone destroying activity" and similarities to insecticides like DDT.

"The broad class of materials we are dealing with here ... contains known or suspected carcinogens," the engineer, James S. Nelson, wrote in a six-page report.

Nelson's report said GE's "largest user" of PCBs was the Industrial and Power Capacitor Department at Hudson Falls.

In 1976, GE prepared another internal report, also never made public, that included the headline: "The Problem." The report said the industry-wide use of PCBs in 1975 was about 13 million pounds, "of which 5.6 million pounds — about 45 percent of industry usage — were used by the Department at Hudson Falls and Fort Edward ... PCBs have been of environmental concern since the late 1960s."

"Gun to your head"

Welch was at the helm when GE began battling the EPA and the state of New York in the 1970s, leading to a two-decades-long debate over the toxicity of PCBs and the effectiveness of dredging. GE vehemently opposed dredging, citing the high cost, potential ecological damage to the river, and the lack of assurances that the plan would work.

Welch holds a doctorate in chemical engineering and, after joining GE at age 24, became vice president of its chemical division in 1973 before his meteoric rise through the company's ranks. During his 20-year tenure as CEO, he was credited with turning GE into one of the world's most profitable companies. But his success was dogged by GE's pollution history, especially the Hudson River.

Welch became personally involved in the company's battle with regulators over PCBs years before he took over the company. He has recounted an incident from December of 1975, when he learned that the state Department of Environmental Conservation was holding a hearing on GE's pollution of the Hudson River, and drove to Albany from his office in Pittsfield, Mass. He said he sat incognito in the back of the hearing room, growing concerned as he watched a GE-hired biologist "coming unglued" as he appeared before regulators.

"He lacked credibility," Welch said in his deposition.

As a result, Welch took over leadership of the PCB battle. Months later, in the spring of 1976, Welch negotiated a settlement with the state of New York that released GE from state liability for the PCB pollution.

The deal called for GE to pay $3 million for monitoring the river's PCB pollution, and $1 million for research.

During his deposition last March, Welch was shown an internal company memo from April 1975.

The memo was attributed to James C. Herger, who was human resources and labor relations director at the Washington County plants in 1975, reporting to the plants' general manager, Lucas Hart. The document, carrying a header from GE's Capacitor Products Department in Hudson Falls, was stamped "strictly private."

"We are again rapidly slipping into a lethargic state of mind concerning our environmental affairs," Herger wrote. "We need to make several changes to abate the discharge of PCBs in kerosines." He also described the company's "lack of priority for environmental projects" and warned that GE's continued violation of an EPA discharge permit "could result in the shutdown of our business."

At the time Welch, a vice president, oversaw the capacitor division as part of his wide-reaching duties. He said last year, though, that he'd never seen Herger's memo and doesn't remember him.

"This fellow thinks we should have had environmental projects at the top of the priorities," Welch said. "I don't know what happened here."

At GE's request, the Herger memo, like thousands of other internal company documents, remains sealed under a court order.

Herger, 75, who left GE in 1979 and lives in Silver Spring, Md., said he met and spoke with Welch on occasion but could not recall writing the memo that's attributed to him in GE's files.

"That strikes me as a suicide note for anybody who works for that company," Herger said in a telephone interview. "Even if I had those concerns, I would not express it like that. ... Why would I have written that letter? That's the equivalent of putting a gun to your head to be an employee (of GE) and write that kind of letter."

Hiring the enemy

In 2004, four years before she became GE's vice president of corporate environmental programs, Ann R. Klee sat before a U.S. Senate environmental committee to make her pitch for confirmation as the EPA's general counsel. Klee was nominated for the position by President George W. Bush, and brought a wealth of legal talent and experience, including several years as a legislative aide on Capitol Hill.

Klee recounted "my most significant case, and certainly one of the highlights of my career" for the Senate panel. In 1990, she said, she had represented the city of Delray Beach, Fla., which had been forced to shut down its public drinking water system due to industrial pollution.

"We were able to identify the source of the contamination — a company that had been dumping used solvents on its property for years — and obtain an $8.7 million verdict ... on behalf of the city for cleanup costs and future operation and maintenance of the treatment structures," Klee told the panel, according to a copy of her statement.

In February 2008, after Klee left the EPA, GE hired her as its vice president of corporate environmental programs. Her job, in part, is overseeing management and clean-up of GE's polluted sites around the country, including the Hudson River. Klee said in a deposition two years ago that she doesn't know if her connections at the EPA were a factor in GE's decision to hire her.

At GE, Klee succeeded Stephen D. Ramsey, who was the Justice Department's environmental enforcement chief before GE hired him in 1990.

Attorneys for the river communities that sued GE have suggested in court filings that GE deliberately hired attorneys like Ramsey and Klee in part due to their government connections. They also have accused GE of plugging attorneys into key corporate positions so their work is categorized as legal advice to a client and thus won't be subject to public disclosure.

More than 20 years ago, at the height of GE's fight against dredging, the company also hired M. Peter Lanahan, a former deputy commissioner in New York's Department of Environmental Conservation. Lanahan was GE's manager of the Hudson River project and personally made presentations to his former agency on behalf of GE, records show.

"Pete was an asset to the company because ... he had great relationships throughout state government, and he was a good project manager," Ramsey said in a deposition. Welch denied that GE was looking to cash in on its executives' government connections.

"We were looking for people that had experience with the agency that they would be dealing with," Welch testified.

"No adverse health effects"

In October 2010, a year after dredging began, the project was suspended so the EPA and GE could evaluate issues that occurred that first year. A major problem was that dredging stirred up more PCBs than predicted. On at least 10 occasions the levels in the upper Hudson River, above the Troy dam, exceeded the 500 parts-per-trillion threshold set by the EPA.

As the negotiations unfolded, Klee wrote an email to the EPA and the Justice Department requesting that documents and charts used in their discussions be kept secret and not made subject to the Freedom of Information Act. The federal agencies declined the request.

"My concern was that if the documents that we exchanged in those discussions were produced in response to a FOIA request, it would be much harder for the parties to engage in an open and honest discussion," Klee testified at a September 2012 deposition in Boston.When dredging resumed, GE and the EPA had agreed to looser rules. Under the new standards, warnings were made to public water suppliers only if the 500 ppt threshold was breached at Rhinebeck — some 60 miles south of the Troy Dam.

The town of Waterford shut down its water treatment plant in 2009 when dredging started. Halfmoon, which opened a $12 million water plant along the river in 2003, kept pumping water from the river but had to turn its plant off repeatedly the first year of dredging.

In March 2010, when there was no dredging, PCB levels in the upper Hudson River spiked to 2,000 ppt, prompting Halfmoon to shut down its plant. It has not used water from the Hudson River since then.

During her 2012 deposition, Klee repeatedly said it's her "understanding" there are "no adverse health effects associated with PCBs." That view conflicts with the stance of her former employer, EPA, which considered PCBs a possible human carcinogen in the 1970s. In the 1990s, the EPA amended its position and said that PCBs are a "probable" human carcinogen.

"It's not part of my responsibility to be a PCB scientist," Klee said, when asked if she'd read reports on PCBs other than those commissioned by GE.

Welch also doesn't believe PCBs have harmful health effects, despite scientific evidence that they may. Much of his position on that, he said, comes from studies that GE commissioned as early as 1976, in which the health trends of its factory workers were studied by scientists.

Last spring, the International Agency for Research on Cancer, which first warned of PCBs' adverse health effects in 1978, declared that certain PCBs, including the type flushed into the river by GE, "have reproductive, toxic, and carcinogenic consequences." The EPA, based on past practice, is expected to adopt that finding once the World Health Organization adopts it.

"EPA," Welch scoffed, waving his hand dismissively during his deposition last year. "I was completely satisfied as to the safety of PCBs. In my time I studied it. I looked at it. I made my judgment and I was completely satisfied. ... I haven't seen any PCB studies that convince me there was another side to it."

But the studies that Welch cites have drawn scientists' questions. In one study commissioned by GE, scientists examined the health patterns of workers at the Washington County capacitor plants and determined that they had a lower rate of cancer than the general population.

"It followed people for only five years ... (and) included all the secretaries, all the people that weren't anywhere near where the PCBs were," said Dr. David O. Carpenter, who has studied PCBs for decades.

"The point about those studies is they were included in the review by the International Agency for Research on Cancer, along with all of the other studies, many of them occupational, and they were found to be unconvincing," said Carpenter, director of the Institute for Health and the Environment at the University at Albany. "The issue is that in addition to cancer, we now have such strong evidence that PCBs alter a large number of other organ systems. PCBs affect the brain and reduce learning ability. This has been demonstrated repeatedly in children exposed to PCBs, often exposed even before birth where they get PCBs from their mother's body and from breast milk."

Learning and memory functions also diminish for adults exposed to PCBs, Carpenter said. He added that some scientists suspect PCBs cause adverse effects to the thyroid glands and health risks that include diabetes, high blood pressure and effects on human reproductive systems.

"PCBs are very dangerous chemicals and anybody that says they are not dangerous simply is not telling the truth, or just does not know what studies have been done," Carpenter said.

Behan, GE's spokesman, questioned Carpenter's credibility.

"Judges in three states have found David Carpenter's opinions too unreliable for a jury to consider as evidence," Behan wrote in an email. "Given this, the Times Union is obliged to re-evaluate whether he is truly qualified to render an opinion on GE's views."

Carpenter, who was retained as an expert witness by the Saratoga County river communities suing GE, has testified in numerous other cases involving PCBs' health effects. He is the founder of the state's School of Public Health and was a member of the World Health Organization panel that last year declared PCBs are a human carcinogen. Carpenter said any compensation he receives as an expert witness is donated to the university's research program.

But not all researchers agree on the dangers of PCBs.

Paul Stewart, a PCB researcher at the State University of New York at Oswego, said the effects on the brain may not be as significant as once believed.

"I tend to see the possible effects of PCBs are far less important than I did when I started this research in 1990s and early 2000s," Stewart said. "The correlations between PCBs and cognitive development are small, even under carefully controlled conditions."

"Alter perception on PCBs"

The alarm sounded at GE in 1990 when the EPA said it was reconsidering its 1984 decision to delay dredging of the river. The federal agency noted mounting evidence that PCBs were a health concern and improvements it said were made in dredging techniques.

On Jan. 17, 1991, an internal team at GE drafted a detailed, confidential plan to take on the EPA.

The 67-page report outlined plans to mount a multimillion-dollar public relations campaign that included a strategy to "establish an intelligence network at regulatory agencies," influence media outlets, and use connections to pressure regulators and elected leaders at all levels of government.

The document, which was stamped "privileged," said the strategy was to "alter perception on PCBs and dredging" and "change regulatory treatment of PCBs."

It highlighted "positive issues" that would be a point of focus, including GE's stated position that PCBs in the Hudson River were becoming "less toxic" through "natural processes" and that "PCBs are overregulated because risk is overstated."

The "basic message," the document states, is that PCBs' "cancer potency factors" were overestimated and that they biodegrade naturally, and are therefore less toxic — notions many scientists dispute. Also, GE would take the position that "neurotoxic effects in children are not attributable to PCBs."

"What GE did was to hire scientists ... who would give GE whatever answer they wanted," said Carpenter, who was previously director of the state Health Department's Wadsworth Center for Laboratories and Research.

Carpenter said the company is correct that anaerobic bacteria remove some chlorine from the PCB molecules. But he said it doesn't destroy or reduce the PCBs. Carpenter reviewed a copy of GE's 1991 strategy report at the request of the Times Union. He pronounced it "full of lies."

"It outlines and shows an intentional strategy to deceive both the government agencies and the general public," he said. "Natural processes in the river were not creating less toxic forms of PCBs, but rather more water soluble and volatile forms that are more toxic for at least some health outcomes."

Behan challenged Carpenter's assessment and said GE's dredging of the river is serving as a national model.

"We simply disagree with his view," Behan said. "That doesn't make anything we've said misleading. We have a disagreement in principle about how he views this issue. ... GE's view is based on the research on the impact of PCBs that have been conducted on the GE workers. It's a view that's based on the interpretation of the science."

Behan also said the debate over the health effects of PCBs "is moot at this point. That ended more than a decade ago. The Hudson River dredging project is now 70 percent complete."

Still, the strategy outline raises questions about whether the company's position on the health effects of PCBs was based on business interests.

Under a section titled "Human Health Effects," the report acknowledges that even if GE could show there were inconclusive cancer studies on PCBs, there was an emerging "new area of concern" on the "neurotoxicological effects" of PCBs. The report mentioned studies showing "minor developmental deficiencies in children of mothers having PCB and other environmental contaminants."

The political targets of GE's campaign included then-Gov. Mario Cuomo, the heads of various state agencies, the EPA, the White House, members of Congress and elected officials from river towns.

On a local level, GE sought to recruit "permanent allies in most local governments above Troy," so the report listed key communities, including those in Saratoga, Washington and Warren counties. In many cases, the plan worked, and local officials initially rallied against dredging.

But whether some public officials understood the implications of their opposition to dredging is questionable.

In June 2012, Stillwater village Mayor Ernest W. Martin Sr. was questioned by a GE attorney as part of the village's lawsuit seeking $12 million for what Martin said was the cost of switching the village water system from a series of underground wells next to the river to a pipeline operated by the county water authority.

The attorney pressed Martin about letters he had written, and public statements he had made, opposing dredging and stating his belief the river was "cleaning itself."

"Well, at the time, it was out there that the river was cleaning itself and the fish and the plant life was all coming back," he testified. "And I was afraid if they stirred up the PCBs, it would just disrupt everything that's going on by cleaning itself."

Martin couldn't cite any report, scientific study or other written materials that led him to oppose dredging. "Common sense," he finally said.

The federal government disagreed.

"Looks can be deceiving," states an EPA web page on the Hudson River's PCB pollution, last updated in 2010. "Yes, the Hudson River looks clean and is teeming with fish. But, the fish and the river bottom on which they depend for food and shelter are contaminated by PCBs. ... The river is not cleaning itself. The PCBs are not safely buried in the sediment. They continue to move as the river flows and each day add to the pollution of the river."

CASE STUDIES IN ENVIRONMENTAL MEDICINE

Polychlorinated Biphenyls (PCBs) Toxicity

Course: WB 2460

Original Date: May 14, 2014

CE Renewal Date: May 14, 2016

Expiration Date: May 14, 2018

Key Concepts	• The highest human exposures to polychlorinated biphenyls (PCBs) occur via the consumption of contaminated fish and, in certain occupational settings, via contact with equipment or materials made before 1977. • Recent studies indicate that maternal consumption of PCB-contaminated fish can cause disturbances in reproductive parameters and neurobehavioral and developmental deficits in newborns and older children. • Evidence shows that exposures to high concentrations of PCBs cause adverse dermal effects in humans. On the basis of sufficient evidence of carcinogenicity in humans and experimental animals, the International Agency for Research on Cancer (IARC) classified PCBs as carcinogenic to humans (Group 1).
About This and Other Case Studies in Environmental Medicine	This educational case study document is one in a series of self-instructional modules designed to increase the primary care provider knowledge of hazardous substances in the environment and to promote the adoption of medical practices that aid in the evaluation and care of potentially exposed patients. The complete series of Case Studies in Environmental Medicine is located on the ATSDR Web site at URL: http: www.atsdr.cdc.gov csem csem.html In addition, the downloadable PDF version of this

	educational series and other environmental medicine materials provides content in an electronic, printable format, especially for those who may lack adequate Internet service.
Acknowledgements	**We gratefully acknowledge the work of the medical writers, editors, and reviewers in producing this educational resource. Contributors to this version of the Case Study in Environmental Medicine are listed below.** **Please Note: Each content expert for this case study has indicated that there is no conflict of interest that would bias the case study content.** **CDC ATSDR Author(s):** Dianyi Yu, MD **CDC ATSDR Planners:** Charlton Coles, PhD; John Doyle, MPA; Kimberly Gehle, MD; Sharon L. Hall, PhD; Michael Hatcher, DrPH; Barbara M. Riley, RN; Delene Roberts, MSA; Brian Tencza, MS; Dianyi Yu, MD. **Peer Reviewers**: Obaid Faroon, DVM, PhD; John Osterich, PhD; Avima M. Ruder, Ph.D.; Anne Sowell, PhD; Mohammed Uddin, MD, MPH.
How to Apply for and Receive Continuing Education Credit, Including the Assessment and Posttest	Visit http: www.atsdr.cdc.gov csem conteduc.html for more information about continuing medical education credits, continuing nursing education credits, and other continuing education units. Access the Assessment and Posttest by selecting http: www2a.cdc.gov TCEOnline registration detailpage.asp?res d 4323
Accrediting Organization	**Credits Offered**

Accreditation Council for Continuing Medical Education	The Centers for Disease Control and Prevention (CDC) is accredited by the Accreditation Council for Continuing Medical Education (ACCME□) to provide continuing medical education for physicians. CDC designates this educational activity for a maximum of **2.0** AMA PRA Category 1 Credits□. Physicians should only claim credit commensurate with the extent of their participation in the activity.
American Nurses Credentialing Center, Commission on Accreditation	CDC is accredited by the American Nurses Credentialing Center's (ANCC) Commission on Accreditation to provide continuing nursing education. This activity provides **2.0** contact hours.
National Commission for Health Education Credentialing, Inc.	CDC is accredited by the National Commission for Health Education Credentialing, Inc. (NCHEC) to provide continuing education contact hours (CECH) in health education. This program is a designated event for the Certified Health Education Specialist (CHES) to receive **2.0** Category I contact hours in health education, CDC provider number GA0082.
International Association for Continuing Education and Training	CDC is approved by the International Association for Continuing Education and Training (IACET), 1760 Old Meadow Road, Suite 500, McLean, VA 22102 to provide continuing education. CDC is authorized by IACET to offer **0.2** IACET continuing education units (CEU) for this program.
National Board of Public Health Examiners	CDC is a pre-approved provider of Certified in Public Health (CPH) recertification credits and is authorized to offer **2.0** CPH recertification credits for this program. CDC is an approved provider of CPH Recertification Credits by the National Board of Public Health Examiners. Effective October 1, 2013, the National Board of Public Health Examiners (NBPHE) accepts continuing education

units (CEU) for CPH recertification credits from CDC. Please select CEU as your choice for continuing education when registering for a course on TCEOnline. Learners seeking CPH should use the guidelines provided by the NBPHE for calculating recertification credits. For assistance please contact NBPHE at http: www.NBPHE.org.

Disclaimer and Disclosure	**Disclaimer** The state of knowledge regarding the treatment of patients potentially exposed to hazardous substances in the environment is constantly evolving and is often uncertain. In developing its educational products, ATSDR has made a diligent effort to ensure the accuracy and the currency of the presented information. ATSDR, however, makes no claim that the environmental medicine and health education resources discussed in these products comprehensively address all possible situations related to various substances. The products are intended for educational use to build the knowledge of physicians and other health professionals in assessing the conditions and managing the treatment of patients potentially exposed to hazardous substances. The products are not a substitute for a health-care provider's professional judgment. Please interpret the environmental medicine and the health education resources in light of specific information regarding the patient and in conjunction with other medical authorities. Use of trade names in ATSDR products is for identification purposes only and does not imply endorsement by the Agency for Toxic Substances and Disease Registry or the U.S. Department of Health and Human Services. **Disclosure** In compliance with continuing education requirements, all presenters must disclose any financial or other associations with the manufacturers of commercial products, suppliers of commercial services, or commercial supporters as well as any use of unlabeled product(s) or product(s) under investigational use. CDC, our planners, and the presenters for this seminar do not have financial or other associations with the manufacturers of commercial products, suppliers of commercial services, or commercial supporters. This presentation does not involve the unlabeled use of a product or product under investigational use. There was no commercial support for this activity.

Table of Contents

How to Use This Course

Introduction	The goal of ATSDR□S CSEM is to increase the primary health care provider□S knowledge of hazardous substances in the environment and to help evaluate and treat potentially exposed patients. This CSEM focuses on PCB toxicity.

Availability	Two versions of the PCB toxicity CSEM are available. • The HTML versionhttp: atsdr-link.cdc.gov csem csem.asp?csem 30 po 0 provides content through the Internet. This version offers interactive exercises and prescriptive feedback to the user. • The downloadable PDF version http: www.atsdr.cdc.gov csem pcb docs pcb.pdf provides content in an electronic, printable format.
Instructions	To make the most effective use of this course: • Take the Initial Check to assess your current knowledge about PCB toxicity. • Read the title, learning objectives, text, and key points in each section. • Complete the progress check exercises at the end of each section and check your answers. • Complete and submit your assessment and posttest response online if you wish to obtain free continuing education credit. You can print your continuing education certificates immediately upon completion.
Instructional Format	This course is designed to help you learn efficiently. Topics are clearly labeled so that you can skip or quickly scan sections with which you are already familiar. This labeling will also allow you to use this training material as a handy reference. To help you identify and absorb important content quickly, each section is structured in the following format.

Section Element	**Purpose**
Title	Serves as a focus question that you should be able to answer after completing the section
Learning Objectives	Describes specific content addressed in each section and focuses your attention on important points
Text	Provides the information you need to answer the focus questions and achieve the learning objectives

Key Points	Highlights important issues and helps you review
Progress Check Exercises	Enables you to test yourself to determine whether you have mastered the learning objectives
Progress Check Answers	Provides feedback to ensure you understand the content and can locate information in the text

Learning Objectives	Upon completion of the PCBs toxicity CSEM, you will be able to meet the objectives as outlined.

Content Area	**Objectives**
Overview	• Describe key characteristics of PCBs
Exposure Pathways	• Identify sources of exposure to PCBs • Identify routes of exposure to PCBs
Who is at Risk	• Identify who is at risk for exposure to PCBs
Standards and Regulations	• Identify EPA's maximum contaminant level (MCL) for PCBs in drinking water • Identify FDA's tolerance levels for PCBs in food
Biological Fate	• Describe characteristics of the metabolism of PCBs in the body
Health Effects	• Describe adverse health effects associated with exposure to PCBs
Clinical Assessment	• Describe characteristic findings on clinical assessment of patients exposed to PCBs • Describe a rational approach for evaluating a patient with a history of occupational and or environmental exposure to PCBs • Describe measurements that can help diagnose exposure to PCBs
Treatment and Management	• Describe the principal treatment strategy for managing PCB poisoning

	• Describe the measures for preventing occupational and environmental exposure to PCBs
Patient Education and Counseling	• Describe instructions appropriate for patients exposed to PCBs

Initial Check

Instructions	This Initial Check will help you assess your current knowledge about PCB toxicity. To take the Initial Check, read the case below and then answer the questions that follow.
Case	**A 48-year-old handyman has progressive cystic acne and abnormal liver function.** A 48-year-old man that you are treating for acne vulgaris returns to your clinic for a follow-up appointment. You first saw this patient about 3 weeks ago. At that time, he had multiple acneiform lesions in the malar and periorbital areas. Both cystic and comedonal lesions were present; most ranged between 3 and 6 millimeters (mm) in diameter, and some were edematous. The patient noted that he was surprised about the development of acne at his age; he never suffered from this condition during adolescence. He had used over-the-counter astringents and anti-acne medications, but they had not affected the lesions. A review of the patient□s medical history indicates that he has • **No** history of hepatitis, • **No** recollection of contact with hepatitis patients, • **No** evidence of liver difficulties, and • **No** record of blood transfusion. The patient has no family history of cardiovascular disease or cancer. The patient does not smoke; he drinks two to three bottles of beer each evening and sometimes more on weekends. He is taking no

medications other than over-the-counter dermatologic medications.

The patient is married and has three teenaged children. His wife and children are in good health. They live in a high-rise apartment building where the patient has been a handyman and part-time building manager for the past year. He spends a lot of time in the basement area, which includes

- Heating facilities,
- A laundry,
- A recreation room with pool table, and
- A workshop.

The patient is an avid fisherman who spends most weekends fishing and eating his catch with his two sons.

At the end of the patient's initial visit, you prescribed a topical antibiotic and instructed the patient on its use. After reassuring the patient that stronger prescription medications are available to treat acne, you ordered a serum biochemical and hematologic profile to document baseline values.

During today's physical examination, you note little or no improvement in the patient's acne. The ratio of cystic to comedonal lesions appears to have increased, and many lesions appear to have become more edematous and erythematous. The patient has several new comedones on his chin, and he points out what appears to be developing areas of folliculitis on his chest and forearms.

In addition to this worsening of the patient's acne, your physical examination of the patient reveals mild, non-tender hepatomegaly without jaundice. This finding causes you to review the results of the biochemical panel. You note the following abnormalities:

- Total bilirubin 2.8 milligrams per deciliter (mg dL) (normal 0 1.5),
- Direct bilirubin 0.4 mg dL (normal 0 0.4),

	• Serum glutamic-pyruvic transaminase (SGPT) (alanine aminotransferase [ALT]) 74 international units per liter (IU L) (normal 0□50), • Serum glutamic-oxaloacetic transaminase (SGOT) (aspartate aminotransferase [AST]) 88 IU L (normal 0□50), • Glutamyl transpeptidase (GGTP or GGT) 190 IU L (normal 15□85), and • Lactate dehydrogenase (LDH) 230 IU L (normal 50□225). The results of all other tests, including the complete blood count, alkaline phosphatase (ALP), blood urea nitrogen, creatinine, and urinalysis, are within normal limits.

Initial Check Questions

1. What should be included in the patient's problem list?

2. What is a differential diagnosis for the patient's altered liver enzymes?

3. What tests would help you arrive at a diagnosis?

4. You persistently pose detailed questions to the patient regarding his work, hobbies, recreational activities, and possible contact with hepatotoxins.

   The patient reveals that he frequently wipes up a "dark, oily discharge" near a large electrical transformer in the work area in the basement workshop. The discharge has produced a gummy residue on tools and other surfaces. He mentions he sometimes feels dizzy and nauseated after working in the basement all day.

   Is this additional information related to the clinical findings?

5. Is there a need to be concerned about exposure to PCBs when the clinical effects in this patient seem so limited?

6. Are other sources of PCB exposure likely for this patient?

7. What confirming laboratory test can be conducted to establish the diagnosis of PCB exposure?

8. The doctor requests a serum PCB analysis. The laboratory reports a level of 125 parts per billion (ppb), with no normal range indicated. How will you interpret this report?

9. What steps should be recommended to patients when PCB-related health effects are suspected?

10. What additional steps should be taken for the situation described in the case study?

Initial Check Answers

1. The patient's problem list includes acne vulgaris, which is atypical because of the location of the lesions and their late onset with no history of outbreaks during adolescence. The mildly altered liver functions are nonspecific but clinically unexpected.

   More information for this answer can be found in the "Clinical Assessment – Signs and Symptoms" section.

2. The combination of asymptomatic hepatomegaly and mild nonspecific elevations of hepatic enzymes suggests a chronic inflammatory liver process or hepatitis. Hepatitis can be drug-induced, toxic, infectious, genetic, or caused by connective tissue disease.

   The major cause of liver disease in the United States is ethanol ingestion. Less commonly, environmental exposures cause either acute or chronic toxic hepatitis. Some connective tissue diseases such as lupus erythematosus are associated with a specific type of hepatitis. Infectious hepatitis includes those attributed to the viruses such as A, B, C, and other possible agents of non-A, non-B hepatitis. Hepatitis can also occur with Epstein-Barr virus and cytomegalovirus infections. Infiltrative diseases such as sarcoidosis or amyloidosis, and rare genetic diseases such as Wilson disease, primary hemochromatosis, and alpha-1-antitrypsin deficiency should be excluded as causes of hepatitis also.

   More information for this answer can be found in the "Clinical Assessment – Laboratory Tests" section.

3. Repeat ALT, AST, GGT, and bilirubin testing; test ALP and prothrombin time; and test for hepatitis viral serologies, heterophil antibody (anti-EBV capsid IgM), anti-nuclear antibody, anti-smooth muscle antibody, and anti-mitochondrial antibody. Consider hemachromatosis (serum ferritin, iron,

and iron binding capacity), Wilson disease (serum copper and ceruloplasmin), and parasitic hepatitis as possible causes of chronic hepatitis.

Assays for suspected hepatotoxins and biopsy of adipose tissue might also be of value. Further evaluation might include ultrasound and percutaneous liver biopsy if other tests do not provide sufficient information.

More information for this answer can be found in the "Clinical Assessment – Laboratory Tests" section.

4. Older electrical transformers and capacitors can contain PCBs as a dielectric and heat-transfer fluid. Leaks in this equipment could allow PCBs to volatilize under conditions of increased temperature. A person with chronic exposure to the vapors or residue could eventually receive a significant PCB dose through both dermal and inhalation routes.

   More information for this answer can be found in the "How Are People Exposed to PCBs?" section.

5. Notably, potential carcinogenicity is the main reason PCB production was banned in the United States. EPA has determined that PCBs are probable human carcinogens and has assigned them the cancer weight-of-evidence classification B2. DHHS concluded that PCBs are reasonably anticipated to be carcinogenic in humans, based on sufficient evidence of carcinogenicity in animals. In February 2013, 26 experts from 12 countries met at the International Agency for Research on Cancer (IARC), Lyon, France, to reassess the carcinogenicity of polychlorinated biphenyls (PCBs). On the basis of sufficient evidence of carcinogenicity in humans and experimental animals, the IARC classified PCBs as carcinogenic to humans (Group 1). The classification is based on

consistent association between PCB exposure and increased risk of melanoma in humans.

More information for this answer can be found in the "What Are the Physiologic Effects of PCBs?" section.

6. In addition to possible dermal and inhalation exposure, the patient might be exposed by consuming contaminated fish, a potential source of PCBs.

   More information for this answer can be found in the "How Are People Exposed to PCBs?" section.

7. Select laboratories have the capability to perform PCB analyses on human tissue. The lipophilic nature of PCBs causes them to accumulate in fat; consequently, analysis of adipose tissue obtained by biopsy has been advocated as a measure of long-term exposure. Serum PCB analysis, which is less invasive than fat biopsy, is readily available. Health risks are not consistent necessarily with PCB levels, but a serum measurement is useful for gauging the patient□s exposure.

   More information for this answer can be found in the "Clinical Assessment – Laboratory Tests" section.

8. A correlation between increasing levels of serum PCBs and dermatologic findings, including chloracne, has not been found consistently in human epidemiologic studies. However, statistically significant associations between dermatologic effects and plasma levels of higher chlorinated PCB congeners have been reported.

   PCB compounds generally can be found at the parts per trillion (ppt) levels in the lipid stores of humans, especially persons living in an industrialized society. The general population is exposed to PCB compounds primarily through the ingestion of high-fat foods such as dairy products,

eggs, animal fats, and some fish and wildlife [CDC 2009b; Hopf et al. 2009; Patterson et al. 2008]. By comparison, the case study patient's PCB serum level of 125 ppb is consistent with PCB exposure as a cause for his unusual acne, and PCB exposure might be contributing to the hepatic effects noted.

More information for this answer can be found in the "Clinical Assessment – Laboratory Tests" section.

9. The first objective should be to stop the exposure. In this case, the patient should stay away from the basement until the transformer is repaired and the basement area is cleaned by a professional familiar with PCB removal. He should also check with his state advisory on PCB-fish contamination and not eat fish from contaminated areas until his PCB level normalizes and the fish are declared uncontaminated. Many states issue advisories on fish consumption based on where the fish are caught. Fish advisories also provide guidance on how to choose fish that are safer to eat and on safer ways to prepare and cook fish. Avoiding exposure is especially important because no specific treatment exists for PCB accumulation. The need to avoid other hepatotoxic substances, including ethanol, should be stressed. Confirmation of exposure with a serum PCB level should be obtained.

   More information for this answer can be found in the "How Should Patients Exposed to PCBs Be Treated and Managed?" section.

10. Because stopping exposure is of prime importance, the physician can be most helpful by advising the patient that proper abatement by professionals is necessary. In this case, the owner of the building should be notified of the potential health hazard and should contact the local public health agency. This might require the assistance of local, state, or federal agencies such as the department of public health and EPA. These agencies can cooperate with

entities involved to ensure remediation of the harmful exposure. It is important to prevent other persons from using the basement areas until cleanup is complete. In addition, the patient should be informed of the availability of fishing and game advisories particular to his state, and he should be encouraged to observe the recommendations of these advisories.

More information for this answer can be found in the "How Should Patients Exposed to PCBs Be Treated and Managed?" section.

What Are Polychlorinated Biphenyls (PCBs)?

Learning Objective

Upon completion of this section, you will be able to

- Describe key characteristics of PCBs.

Definition

PCBs are chemicals formed by attaching one or more chlorine atoms (at the Xs in Figure 1 below) to a pair of connected benzene rings.

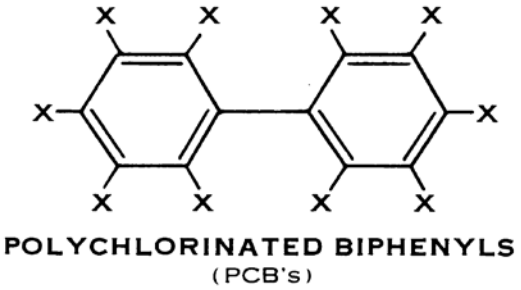

Figure 1: Polychlorinated Biphenyls (PCBs)

Depending on the number and position of chlorine atoms attached to the biphenyl ring structure, 209 different PCB congeners can be formed. PCB congeners can be divided into the coplanar, the mono-ortho-substituted PCBs, and other non-dioxin-like PCBs. The significance of this designation is that coplanar and some of the mono-ortho-substituted PCBs have dioxin-like toxicologic effects.

Chemical Properties: Dioxin-like vs. Non-dioxin-like	The chlorination pattern of the PCBs determines the toxicity of the substance. A number of PCB congeners show **dioxin-like** toxicity. These PCBs have no more than one chlorine atom at the ortho-position (polychlorinated non-ortho and mono-ortho biphenyls). The phenyl rings of these molecules can rotate and adopt a coplanar structure, which leads to the same toxicity as the polychlorinated dibenzo-p-dioxins (PCDDs) and polychlorinated dibenzofurans (PCDFs). The toxic effects of these dioxin-like PCBs are discussed in detail in later sections of this document. A number of PCB congeners, however, have two or more of the ortho-positions in the biphenyl molecules occupied by chlorine molecules. For these, the two phenyl rings are not in the same plane, and these PCBs express **non-dioxin-like** toxicity. Commercial PCB products are mixtures of different PCB congeners and contain small amounts of PCDFs or PCDDs. Contamination is a concern because the toxicity of these contaminants is generally much greater than that of PCBs [ATSDR 2000].
Uses	Because of their insulating and nonflammable properties, PCBs were marketed for nearly 50 years between 1929 and 1977. They were used in making • Diffusion pump oils, • Extenders for pesticides, • Heat exchange and dielectric fluids in transformers and capacitors, • Hydraulic and lubricating fluids, and • As ingredients in caulking compounds, paints, adhesives, flame retardants, and plasticizers. In 1977, the United States banned production of PCBs because of their potential carcinogenicity.
Trade Names	The following trade names are used for commercial PCB mixtures: • Aroclor

	• Asbestol • Askarel • Clorphen • Diaclor • Dykanol • EEC-18 • Eucarel • Nepolin • Pyranol
Key Points	• PCBs are manufactured chemicals that were produced for nearly 50 years in the United States before they were banned in 1977. • PCBs were banned because of their potential carcinogenicity.
Progress Check	1. Select the best answer from the following choices: A. Commercial PCB products are mixtures of different PCB congeners. B. Commercial PCB products commonly are contaminated with small amounts of polychlorinated dibenzofurans (furans) or polychlorinated dibenzodioxins (dioxins). C. PCB manufacturing was banned in the United States in 1977. D. All of the above. *To review relevant content, see "Chemical Properties and Uses" in this section.*

Where Are PCBs Found?

Learning Objective	Upon completion of this section, you will be able to • Identify sources of exposure to PCBs.

Introduction	No known natural sources of PCBs exist. The United States banned production of these chemicals in 1977, when their ability to accumulate in the environment and to cause harmful effects became apparent [ATSDR 2000]. Today, the major source of exposure to ambient PCBs is environmental cycling of PCBs previously released into the environment.
Released Into the Environment	Between 1929 and 1977, more than 1.25 billion pounds of PCBs were produced in the United States [ATSDR 2000]. PCBs can be released into the general environment by or from • Disposal of PCB-containing consumer products in municipal landfills • Illegal or improper dumping of waste that contained PCBs, such as transformer fluids • Leaks (fugitive emissions) from electrical transformers and capacitors containing PCBs • Poorly maintained toxic waste sites Once released into the environment, PCBs • bioaccumulate and biomagnify as they move up the food chain, • degrade relatively slowly, and • are cycled and transported within the ecosystem [ATSDR 2000; Safe 2007]. PCBs have been identified in at least 500 of the 1,598 hazardous waste sites on the EPA□S National Priorities List, and low levels of PCBs can be found throughout the world [ATSDR 2000].

Environmental Contamination	Once released into the environment, PCBs adsorb strongly to soil and sediment. As a result, these compounds tend to persist in the environment, with half-lives for most congeners ranging from months to years. PCBs leach from soil slowly, particularly the more highly chlorinated congeners, and translocate to plants via soil insignificantly. Cycling of PCBs through the environment involves volatilization from land and water surfaces into the atmosphere, with subsequent removal from the atmosphere by wet or dry deposition, then revolatilization. In the general population, inhalation of these airborne PCBs is one route of exposure, in addition to the food source of exposure to PCBs.
Key Points	• Environmental contamination from PCBs has been caused by accidental releases, careless disposal practices, and leaks from industrial facilities or chemical waste-water disposal sites. • PCBs degrade very slowly, are cycled and transported within the ecosystem, and bioaccumulate as they move up the food chain.
Progress Check	2. Once released into the environment, PCBs may undergo all of the following **EXCEPT** A. Volatilization from land and water surfaces into the atmosphere B. Biotransformation into more complex undefined mixtures C. Fast degradation within the ecosystem D. Strong adsorption to soil and sediment *To review relevant content, see "Released into Environment" in this section.*

What Are Routes of Exposure for PCBs?

Learning Objective	Upon completion of this section, you will be able to

	• Identify routes of exposure to PCBs.
Introduction	Although PCBs are no longer manufactured in the United States, people can still be exposed to them. The two main sources of exposure to PCBs are the environment and the workplace. Because they are resistant to degradation, highly chlorinated PCB compounds can persist in the environment for decades. However, over the past two decades, concentrations of PCBs in most environmental media generally have decreased.
Non-Occupational Exposure: • **General Population**	Food is the main source of exposure to PCBs for the general population (CDC 2009b). Exposure occurs primarily by ingesting high-fat foods□such as dairy products, eggs, and animal fats□and some fish and wildlife [ATSDR 2000; CDC 2009b; Fisher 1999; Gunderson and Gunderson 1988; Hopf et al. 2009; Patterson et al. 2008]. CDC publishes the National Report on Human Exposure to Environmental Chemicals. This report is an ongoing assessment of the exposure to environmental chemicals in the general U.S. population. The Fourth Report (CDC 2009b) contains data for years 1999□2000, 2001□2002, and 2003□2004 from participants in National Health and Nutrition Examination Survey (NHANES). Detailed information on NHANES is available at http: www.cdc.gov nchs nhanes about□nhanes.htm . Serum concentrations of PCBs were found to reflect cumulative past exposure in the general U.S. population [ATSDR 2011].

• **Bio-accumula-tion and Dietary Exposure**	In aquatic environments, the high lipophilicity of PCBs causes these compounds to partition out of the water and become adsorbed preferentially to sediments. Although sediment adsorption helps prevent the contamination of drinking-water supplies, the partitioning of PCBs to sediments plays a role in the tendency of these compounds to become concentrated in aquatic organisms. Bottom-feeding fish ingest and accumulate PCBs from sediment. The resistance of these compounds to biodegradation causes PCBs to become more concentrated as they move upward through the food chain from the bottom-feeding organisms. As a result of this bioconcentration and biomagnification, PCB levels in aquatic organisms can be as much as one million times higher than the levels in the aquatic environment [ATSDR 2000]. In the National Study of Chemical Residues in Fish conducted between 1986 and 1989 [EPA 1992a, 1992b], the mean concentration of PCBs in bottom-feeding and game fish was 1.9 parts per million (ppm). However, PCB levels as high as 20 ppm have been detected in game fish taken from waters near hazardous waste sites [ATSDR 2000].
• **FDA Studies**	The U.S. Food and Drug Administration (FDA)□S Total Diet Studies have revealed that total PCB levels have shown a downward trend in concentration from the middle 1970s to the middle 1980s and a relatively steady intake from 1982 to 1997. For example, total diet studies conducted from 1982 to 1984 for adults between the ages of 25 and 30 indicated that the mean daily intake of PCBs was 0.001 micrograms kilograms (µg/kg) body weight day while in the 1997 study, the mean was 0.002 µg/kg body weight/day [ATSDR 2000].
Non-Occupational Exposure: • **Special populations**	People living near incinerators, other PCB-disposal facilities, or NPL hazardous waste sites where PCBs have been detected may receive higher PCB exposures than the general population. These exposures may be through ingestion, inhalation, or skin contact [ATSDR 2000].

	Do-it-yourselfers repairing or removing older construction materials, including plaster, paint, and caulk, that contain PCBs.
Occupational Exposures:	Occupational exposure to PCBs occurs mainly via the inhalation and dermal routes.
• **Inhalation and Dermal**	Commercial PCB mixtures vary from colorless to dark brown oils, and from viscous liquids to sticky resinous semisolids. Although PCBs evaporate slowly at room temperature, the volatility of PCBs increases dramatically with even a small rise in temperature. Equipment that contains PCBs can overheat and vaporize significant quantities of these compounds, creating an inhalation hazard that can be magnified by poor ventilation. Because of their highly lipophilic nature, PCBs also can be absorbed through the skin following contact with contaminated equipment, water, or soil. Products that contain PCBs are no longer manufactured, thus occupational exposure no longer occurs in those settings. However, it might occur • During the maintenance or repair of old equipment that contains PCBs, • As a result of accidents involving such equipment [Schecter AJ and Charles 1991; Wolff 1985], or • During waste-site cleanup or disposal activities [ATSDR 2000; Luotamo et al. 1993; Schecter A et al. 1994]. • During repair or removal of older construction materials, including plaster, paint, and caulk that contain PCBs. Today, PCBs are found mainly in transformers and capacitors manufactured before 1977. Such transformers and capacitors might be found in • Old industrial equipment (e.g., welding equipment), • Medical equipment (e.g., x-ray machines), and

	• Household appliances (e.g., refrigerators, microwaves and televisions).
Key Points	• The primary route of exposure to PCBs in the general population is the consumption of contaminated foods, particularly meat, fish, and poultry. • Occupational exposure to PCBs occurs mainly via the inhalation and dermal routes. o Although occupational exposure no longer occurs as a result of the manufacture of PCB-containing products, it might still occur during the maintenance or repair of equipment manufactured before 1977 that may contain PCBs or as a result of accidents involving such equipment. o Occupational exposure might also occur during waste-site cleanup or disposal activities.
Progress Check	3. Which of the following statements is **NOT CORRECT**? A. The primary route of exposure to PCBs in the general population is consuming contaminated foods. B. Over the past two decades, the general overall trend is decreasing concentrations of PCBs in most environmental media. C. Over the past two decades, PCB body burdens in humans have shown no changes. D. Occupational exposure to PCBs occurs mainly via the inhalation and dermal routes. *To review relevant content, see "Non-occupational and Occupational Exposure Routes" in this section.*

Who Is at Risk of Exposure to PCBs?

Learning Objective	Upon completion of this section, you will be able to • Identify who is at risk of exposure to PCBs.

Introduction	People with potentially high exposures to PCBs include • Recreational and subsistence fishers who typically consume larger quantities of locally caught fish than the general population, • Children with in utero and lactational exposure to PCBs from mothers who eat large quantities of contaminated fish during pregnancy and while nursing, • Certain farmers and their families who consume PCB-contaminated food via their own farm-raised beef and dairy cattle, and • People living near incinerators, other PCB-disposal facilities, or NPL hazardous waste sites where PCBs have been detected. Although PCBs are no longer manufactured in the United States, workplace exposure potentially may exist. In occupational settings, persons who repair and maintain equipment with capacitors and transformers manufactured before 1977 could be exposed to PCBs.
Recreational and Subsistence Fishers	Due to the factors of culture and lifestyles, sport anglers and subsistence fishers may consume 10 times more fish and seafood than average U.S. consumers. Many of these subsistence fishers are American Indian, ethnic minority, or immigrant populations. The special dietary practices of these populations can lead to significant exposures to persistent pollutants [Hovinga et al. 1993; Judd et al. 2004].

Children with Maternal Exposures	**Children of mothers who eat large quantities of contaminated fish may be exposed to PCBs prenatally and while breastfeeding.** Several studies have reported that prenatal exposure to PCBs has been confirmed among children of consumers of contaminated fish and certain other groups [Fein et al. 1984; Jacobson JL et al. 1990b; Jacobson SW et al. 1985; Swain and Swain 1991]. Other studies have indicated that lactating women whose diets are high in PCB-contaminated fish potentially can increase the PCB exposure for their breastfeeding infants [Dewailly et al. 1989; Fitzgerald et al. 1998; Greizerstein et al. 1999; Rogan et al. 1985]. Fetuses and neonates are more sensitive to PCBs than are adults. During these early life stages, the hepatic microsomal enzyme systems that facilitate the metabolism and excretion of PCBs are not fully functional.
Farming Families	**Farmers and their families who consume PCB-contaminated food via their own farm-raised beef and dairy cattle may be exposed.** During the 1940s and 1950s, the insides of concrete silos on many farms in the Midwest United States were coated with sealants containing PCBs. Over time, these sealants peeled off and became mixed with silage used to feed beef and dairy cattle. Farmers and their families who lived on these farms and who regularly ate farm-raised beef and dairy products were exposed to PCBs. Although most of these silos have been dismantled and removed, the remaining silos represent a potential source of exposure to PCBs [Hansen 1987; Humphrey 1983; Schantz et al. 1994].

People Living Near PCB Contaminated Sites	**Persons living near incinerators, other PCB-disposal facilities, or NPL hazardous waste sites where PCBs have been detected may be exposed.** Persons living near incinerators, other PCB-disposal facilities, or any of the 500 current or former hazardous waste sites on the NPL sites where PCBs have been found may be also at increased risk for exposure to PCBs [ATSDR 1987; Hazdat 2000; Hermanson and Hites 1989; Robertson and Ludewig 2011; Stehr-Green et al. 1988; Wester et al. 1993].
Persons with Impaired Hepatic Function	PCBs are metabolized mainly in the liver, thus, persons with impaired hepatic function might be at increased risk because their ability to detoxify and excrete these compounds is diminished. Persons with incompletely developed glucuronide conjugation mechanisms (such as Gilbert syndrome or Crigler-Najjar syndrome) have impaired liver function, as do persons with chronic liver diseases such as cirrhosis or hepatitis B [Calabrese et al. 1977; Lester et al. 1964]. Similarly, because hepatic function normally declines with age, elderly persons may be more susceptible to the effects of exposure to PCBs.
Children's Susceptibility	Infants and young children consume a greater amount of food per kilogram of body weight than do adults. Therefore, they have proportionately greater exposure to PCBs than do adults eating food with the same level of contamination [ATSDR 2000]. In addition, as mentioned earlier, fetuses and neonates are potentially more sensitive to PCBs than are adults because their hepatic microsomal enzyme systems that facilitate the metabolism and excretion of PCBs are not fully functional.
Exposure in the Workplace	PCB levels in blood and body tissues were 10–1,000 times higher in persons exposed to PCBs in the workplace than in non-occupationally exposed persons [Kreiss and Kreiss 1985; Wolff 1985; Yakushiji et al. 1978].

The United States no longer produces PCBs or products containing PCBs (e.g., capacitors, transformers, and electrical equipment), thus occupational exposure to PCBs no longer occurs in those settings. However, workers can have inhalation or dermal contact with PCBs when repairing or performing routine maintenance on older equipment or electrical transformers, and during accidents or spills involving PCBs [Fait et al. 1989; Schecter AJ and Charles 1991; Welsh 1995; Wolff 1985]. Exposure can also occur during the disposal of materials containing PCBs at hazardous waste sites, waste-site cleanup, or demolishing buildings containing PCBs [Luotamo et al. 1993; Robertson and Ludewig 2011].

Specific occupations with risk for exposure to PCBs in the National Occupational Exposure Survey (NOES)[NIOSH 1989] include

- Construction work,
- Demolition work,
- Electric cable repair,
- Electroplating,
- Emergency response,
- Firefighting,
- Hazardous waste hauling or site operation,
- Heat exchange equipment repair,
- Maintenance or cleaning,
- Medical laboratory technician or technologist,
- Metal finishing,
- Non-cellulose fiber industry,
- Paving and roofing,
- Pipefitting or plumbing,
- Semiconductor and related industries,
- Timber products manufacturing,
- Transformer or capacitor repair, and
- Waste-oil processing.

Key Points

- Recreational and subsistence fishers who consume large amounts of contaminated fish may be at increased risk for high-level exposure to PCBs.
- Populations with increased exposure to PCBs include

- Children of mothers who eat large quantities of contaminated fish during pregnancy and while nursing;
- Farm families who eat PCB-contaminated food; and
- Persons who live near incinerators, other PCB-disposal facilities, or NPL hazardous waste sites where PCBs have been detected.

- Persons with compromised hepatic function might metabolize PCBs less efficiently than healthy persons.
- Although the United States no longer manufactures PCBs, workers can be exposed to PCBs during repair of equipment manufactured before 1977, accidents or spills involving PCB, and waste-site cleanup or disposal activities.

Progress Check

4. Of the following, who may be at increased risk of high-level exposure to PCBs?

   A. Sport anglers and subsistence fishers.
   B. Workers whose jobs include routine maintenance of equipment or electrical transformers manufactured before 1977.
   C. The children of mothers who eat large quantities of contaminated fish during pregnancy and while nursing.
   D. All of the above.

   To review relevant content, see all topics in this section.

What Standards and Regulations Exist for PCB Exposure?

Learning Objective

Upon completion of this section, you will be able to

- Describe EPA's maximum contaminant level (MCL) for PCBs in drinking water.
- Describe FDA's tolerance levels for PCBs in food.

Introduction	The U.S. government has developed standards and regulations for PCBs that are designed to protect the public and workers from potential adverse health effects.
Workplace Standards	**Air** The Occupational Safety and Health Administration (OSHA)☒ permissible exposure limit (PEL) is a time-weighted average (TWA) airborne concentration of 1.0 milligrams per cubic meter (mg m^3) for PCBs containing 42☐ chlorine (average molecular formula of $C_{12}H_7Cl_3$). The PEL for PCBs with 54☐ chlorine and an average molecular formula of $C_{12}H_5Cl_5$ is 0.5 mg m^3 (OSHA 1998a). Both standards encompass all physical forms of these compounds: • Aerosols, • Vapor, • Mist, • Sprays, and • PCB-laden dust particles. OSHA recognizes that PCBs can be absorbed through intact skin; therefore, both dermal and inhalation exposure routes should be evaluated by an industrial hygienist. The National Institute for Occupational Safety and Health (NIOSH)FDA recommends a 10-hour TWA of 1.0 micrograms per cubic meter (µg/m^3) based on the minimum reliable detectable concentration and the potential carcinogenicity of PCBs [NIOSH 2005]. NIOSH also recommends that all workplace exposures be reduced to the lowest feasible level.

Environmental Standards

Drinking Water

EPA considers PCBs a probable human carcinogen and prohibits industrial discharges under the Clean Water Act Effluent Guidelines.

EPA's goal for drinking water's maximum contaminant level is zero, and the enforceable MCL for PCBs in public water systems is 0.0005ppm [EPA 2001].

EPA requires that PCB spills or accidental releases into the environment of 1 pound or more be reported to EPA [ATSDR 2000].

Food

FDA mandates tolerances of 0.2–3.0 ppm PCBs for all foods, with a tolerance level in fish of 2 ppm. FDA also limits PCBs in paper food-packaging materials to 10 ppm [FDA 1996c].

The Food and Agriculture Organization (FAO) and the World Health Organization (WHO) allow a daily PCB intake of 6 µg/kg per day [AAP 2003].

Table 1. Standards, regulations, and recommendations for PCBs

Agency	Focus	Level	Comments
OSHA	Air: workplace	1.0 mg m^3 for PCBs with 42% Cl 0.5 mg m^3 for PCBs with 54% Cl	Enforceable; TWA, PEL Both standards encompass all physical forms of aerosols, vapor, mist, sprays, and PCB-laden dust particles.
NIOSH	Air: workplace	1.0 µg/m^3	Advisory; TWA (10-hour)

	EPA	Drinking water: environment	0.0005 ppm	Enforceable MCL□
	FDA	Food: environment	0.2□3.0 ppm (all foods) 2.0 ppm (fish) 10 ppm (paper food-packaging materials)	Enforceable; Tolerance level
	WHO FAO	Food: environment	6.0 µg/kg per day	Allowable daily intake
	□TWA (time-weighted average): TWA concentration for a normal workday and a 40-hour workweek to which nearly all workers may be repeatedly exposed □PEL (permissible exposure limit): highest level of PCBs in air to which a worker may be exposed, averaged over an 8-hour workday □MCL (maximum contaminant level): enforceable level for drinking water µg/kg: microgram per kilogram µg/m^3: microgram per cubic meter ppm: parts per million			
Key Points	• OSHA□s PEL is 1,000 µg/m^3 for PCB mixtures 42□ chlorinated and 500 µg/m^3 for compounds 54□ chlorinated. • EPA□s enforceable MCL for PCBs in public drinking-water systems is 0.0005 ppm. • FDA□s tolerance levels for PCBs in food range between 0.2 and 3 ppm.			

Progress Check	5. Which of the following statements is **FALSE** regarding U.S. standards for PCBs levels? A. EPA has set an enforceable MCL for PCBs in public drinking water systems. B. EPA considers PCBs a probable human carcinogen and prohibits industrial discharges under the Clean Water Act Effluent Guidelines. C. FDA has banned PCBs in paper food-packaging materials. D. NIOSH recommends that all workplace exposures to PCBs be reduced to the lowest feasible level. *To review relevant content, see "Environmental Standards" in this section.*

What Is the Biologic Fate of PCBs in Humans?

Learning Objective	Upon completion of this section, you will be able to • Describe the characteristics of PCB metabolism in humans.
Introduction	Rates of PCB metabolism vary greatly with the degree of chlorination of the biphenyl rings and the positions of the chlorines on these rings. In the environment, PCBs undergo environmental alterations through • Partitioning, • Chemical transformation, and • Preferential bioaccumulation. As a result, compositions of environmental PCB mixtures differ from commercial PCB mixtures (original Aroclors).

Absorption and Distribution	Humans can absorb PCBs by the: • Inhalation, • Oral, and • Dermal routes of exposure. Although PCBs are readily absorbed into the body, they are slowly metabolized and excreted. PCBs initially distribute preferentially to the liver and muscle tissue. PCBs, especially the highly chlorinated congeners, tend to accumulate in lipid-rich tissues due to their lipophilic nature. Greater relative amounts of PCBs are usually found in • Adipose tissue, • Breast milk, • The liver, and • Skin [ATSDR 2000; Matthews et al. 1984].
Metabolic Pathways	The liver is the primary site of metabolism of PCBs, which occurs via hydroxylation and conjugation with glucuronic acid and sulfates. PCBs are metabolized by the microsomal monooxygenase system catalyzed by cytochrome P-450 to phenols (via arene oxide intermediates), which can be conjugated or further hydroxylated to form a catechol [Safe SH 2007]. Glucuronide and sulfate conjugates are excreted mainly in the urine, whereas hydroxylated metabolites are excreted mainly in the bile. The rate of individual congener metabolism depends on the number and position of chlorine atoms. Steele et al. estimated the half-life in humans for lower chlorinated biphenyls (Aroclor 1242) as 6□7 months and the corresponding half-life for the more highly chlorinated biphenyls as 33□34 months [Steele et al. 1986]. Phillips et al. measured total PCBs in capacitor workers and calculated half lives of 2.6 and 4.6 years for the lower (Aroclor 1242) and higher (Aroclor 1254) chlorinated

	biphenyls, respectively [Phillips et al. 1989]. A more recent study, taking into account of high initial body burden, ongoing environmental exposure, low serum levels, and congeners with very long half-lives, has showed the estimated half-lives during a period of high internal dose were 1.74 years for Aroclor 1242 and 6.01 years for Aroclor 1254. Half-lives during a period of low internal dose were estimated to be 21.83 years and 133.33 years for Aroclor 1242 and Aroclor 1254, respectively [Hopf et al. 2013]. In general, less-chlorinated PCB congeners are more readily metabolized than are highly chlorinated congeners. As a result of this preferential metabolism, highly chlorinated congeners tend to remain in the body longer than do less-chlorinated congeners. Highly chlorinated congeners therefore tend to become more concentrated in adipose tissues, where they are stored in solubilized form.
Excretion	PCBs are primarily excreted after they have been conjugated and transformed into more polar metabolites. The major routes of excretion of PCBs are fecal and urinary.

Environmental Alteration of PCB Mixtures	Environmental PCBs occur as mixtures whose compositions differ from the commercial mixtures. This is because after release into the environment, PCB mixture composition changes over time through chemical transformation and preferential bioaccumulation [Cogliano 1998]. Chemical transformation can occur through biodegradation of PCB mixtures in the environment. PCBs with higher chlorine content are extremely resistant to oxidation and hydrolysis. Preferential bioaccumulation occurs in living organisms. Bioaccumulation through the food chain tends to concentrate congeners of higher chlorine content. In humans, bioaccumulated PCBs also appear to be more persistent in the body [Hovinga et al. 1992]. This is significant because bioaccumulated PCBs appear to be more toxic than original Aroclors in animals [Aulerich et al. 1986; Cogliano 1998].
Key Points	• PCBs are stored in adipose tissues. • The liver is the primary site of metabolism of PCBs. • The slow metabolism and high lipid solubility of PCBs lead to bioaccumulation. • Binding of PCB metabolites to nucleophilic cellular macromolecules may contribute to the toxic effects of PCBs. • After release into the environment, PCBs occur as mixtures whose compositions differ from the commercial mixtures. Bioaccumulated PCBs also appear to be more persistent in the body.
Progress Check	6. Which of the following statements about the biologic fate of PCBs is **NOT CORRECT**? A. The liver is the primary site of PCBs metabolism, which occurs via hydroxylation and conjugation with glucuronic acid and sulfates. B. Less-chlorinated congeners are more readily metabolized than are highly chlorinated congeners. C. Highly chlorinated congeners tend to become more concentrated in muscle.

D. Bioaccumulated PCBs appear to be more persistent in the body.

What Are Adverse Health Effects of PCB Exposure?

Learning Objective

Upon completion of this section, you will be able to

- Describe adverse health effects associated with exposure to PCBs.

Introduction

Human exposures to relatively high levels of PCBs have occurred primarily in persons working in plants that extensively manufactured and used PCBs and PCB-containing equipment. Occupational exposure to PCBs can result in a broad spectrum of effects that includes

- Increased levels of some liver enzymes, with possible hepatic damage,
- Chloracne and related dermal lesions, and
- Respiratory problems [Alvares et al. 1977; Chase et al. 1982; Emmett and Emmett 1985; Lawton et al. 1985; Meigs 1954; Ouw et al. 1976; Safe S 1993; Warshaw et al. 1979].

Potential adverse human health effects of low-level environmental exposure to PCBs are complex and still need further validation [Safe SH 2007].

In animal studies, commercial PCBs elicit a broad range of toxic responses including:

- Acute lethality,
- Body weight loss,
- Carcinogenesis,
- Dermal toxicity,
- Fatty liver,
- Genotoxicity,
- Hepatomegaly,
- Immunosuppressive effects,
- Neurotoxicity,

	• Porphyria, • Reproductive and developmental toxicity, • Thymic atrophy, and • Thyroid hormone-level alterations. This adverse health effects section addresses PCBs as a whole.
Mechanism of PCB Toxicity	PCBs are metabolized by the microsomal monooxygenase system catalyzed by cytochrome P-450 to phenols (via arene oxide intermediates), which can be conjugated or further hydroxylated to form a catechol. Arene oxide intermediates are electrophilic in nature. They can covalently bind to nucleophilic cellular macromolecules (e.g., protein, DNA, RNA) and induce DNA strand breaks and DNA repair, which can contribute to the toxic response of PCBs. Additionally, arene oxide intermediates can be conjugated with glutathione and further metabolized to form methylsulfonyl metabolites, which have been identified in human serum and tissue samples and in laboratory animals. Binding of methylsulfonyl metabolites to some proteins may contribute to some of the toxic effects of PCBs. It has also been hypothesized that hydroxylated PCB metabolites could contribute to the toxicity of PCBs [ATSDR 2000; Safe SH 2007].

Dermatologic Effects	Chloracne and related dermal lesions have been reported in workers occupationally exposed to PCBs. Mild to moderate chloracne was observed in 7 of 14 workers exposed to 0.1 mg m□Aroclors for an average duration of 14.3 months [Meigs 1954]. Among 80 workers who manufactured capacitors in Italy, 10 cases of acne or folliculitis, or both, and 5 cases of dermatitis were reported. All of the workers with chloracne were employed in high exposure jobs. Their blood PCB concentrations ranged from 41 to 1319 □g kg [Maroni et al. 1981]. In a person with PCB-induced chloracne, the acne-like lesions arise as a result of inflammatory responses to irritants in the sebaceous glands. Chloracne usually begins with the formation of keratin plugs in the pilosebaceous orifices. The resulting inflammatory folliculitis stimulates keratinization of the sebaceous gland ducts and outer root sheath of the hair, leading to the formation of keratin cysts. The chin, periorbital, and malar areas are most often involved, although lesions might also appear in areas not usually affected by acne vulgaris (e.g., the chest, arms, thighs, genitalia, and buttocks). The most distinctive lesions are cystic and measure 1□10 mm, although comedonal lesions can also be present. The cysts and comedones can become inflamed and secondarily infected, and papules and cysts can be surrounded by edema and erythema [Crow 1970; Letz 1983]. Chloracne generally indicates systemic toxicity and can be caused by not only dermal contact but also ingestion of PCBs. However, the absence of chloracne does not rule out exposure [Kimbrough 1980; Letz 1983]. No reliable dose-response model exists for chloracne in exposed populations, and the dose-response relationship might be dependent on individual predisposition. Chloracne typically develops weeks or months after exposure. The lesions are often refractory to treatment and can last for years or decades.

	In addition to chloracne, other dermal effects noted in some PCB-exposed workers include pigmentation disturbances of skin and nails, erythema and thickening of the skin, and burning sensations [Fischbein et al. 1982; Fischbein et al. 1979; Ouw et al. 1976; Smith et al. 1982]. Skin effects were reported widely among victims of the Yusho (Japan) and Yu-Cheng (Taiwan) poisoning episodes in 1968 and in 1978, respectively. In these episodes, persons were exposed to PCBs and their heat-degradation products, mainly polychlorinated dibenzofurans (PCDFs). Exposure to PCBs occurred by consuming rice oil that had become contaminated by heat-degraded PCBs during processing. Unlike usual PCB mixtures, the Yusho and Yu-Cheng mixtures were heated in thermal heat exchangers during the cooking process, resulting in contamination of the oil by chlorinated dibenzofurans as well as PCBs. This co-contamination created controversy [Anonymous 1997; Kimbrough et al. 2003; Ross 2004] about the extent to which the health effects observed in the Yusho and Yu-Cheng populations can be attributed to PCBs legitimately, as opposed to the dibenzofuran co-contaminants. No adverse dermal effects have been reported in persons who consume large amounts of Great Lakes fish contaminated with PCBs and other environmentally persistent chemicals, or in other cohorts from the general population. However, whether this outcome was systematically studied in these cohorts is unknown [ATSDR 2000]. A skin lesion exactly like chloracne in humans has been observed in several species of animals experimentally exposed to PCBs [Allen 1975]. After monkeys incur long-term oral exposure to commercial PCB mixtures, related dermal effects are well characterized and generally are similar to those observed in humans [ATSDR 2000].
Key Points	• Conclusive evidence that exposure to PCBs induces adverse dermal effects in humans exists.

	• A typical dermal sign of exposure is chloracne.
Reproductive and Developmental Effects	Courval, DeHoog et al. [1999] conducted a study of 626 married couples in Michigan. The relative risk of conception failure (defined as inability to conceive after 12 months) rose in men but not in women with increasing consumption of PCB-contaminated fish. Some evidence shows that increased intake of PCB-contaminated fish can shorten menstrual cycle length, but no adverse association was found between the duration of fish consumption and time-to-pregnancy in the same population. In a study of 1,820 multigravida women, no significant association was found between low-to-moderate PCB intake and clinically recognized spontaneous fetal death [Mendola et al. 1995]. A recent oocupational cohort study examined the data from 2595 live births of female workers from three capacitor plants and found no evidence of altered sex ratio among children born to PCB-exposed female workers [Rocheleau et al. 2011]. The first epidemiologic investigation to demonstrate an association between the amounts of PCB-contaminated fish eaten by pregnant women and behavioral deficits in their newborns was the Michigan Maternal Infant Cohort Study, published in 1984 [Fein et al. 1984; Jacobson SW et al. 1985]. In this study, developmental and cognitive deficits were observed in the children of mothers who had eaten moderate to high amounts of contaminated fish during the six years preceding pregnancy and who continued to do so during pregnancy. Developmental effects in this population included statistically significant decreases in • Gestational age (4.9 days), • Birth weight (160□190 grams), and • Head circumference (0.6 centimeters). In addition, infants born to mothers who had eaten the greatest amount of contaminated fish during pregnancy exhibited weaker reflexes, greater motor immaturity,

and more pronounced startle responses compared with infants born to women who had consumed less fish.

It is essential that women of childbearing age be aware of fish advisories to ensure they not only limit their consumption of fish with elevated PCB levels but also learn how to prepare fish to limit their PCB ingestion.

Follow-up studies of the children from this cohort have demonstrated that the effects of perinatal exposure to PCBs are persistent. At four years of age, these children still had deficits in

- Weight gain,
- Depressed responsiveness, and
- Reduced performance on the visual recognition-memory test.

At 11 years of age, the children of highly exposed mothers were

- Three times more likely than controls to have low full-scale verbal IQ scores,
- Twice as likely to lag behind at least 2 years in reading comprehension, and
- More likely to have difficulty paying attention [Jacobson JL et al. 1990a, 1990b].

Recent studies indicate that maternal consumption of PCB-contaminated fish can cause disturbances in reproductive parameters and neurobehavioral and developmental deficits in newborns and older children. Prenatal exposure to PCBs from the mother□s body burden, rather than exposure through human milk, is believed to account for the developmental effects of these compounds [Jacobson JL et al. 1996; Longnecker et al. 2003; Ribas-Fito et al. 2001; Schantz et al. 2003].

Similar reproductive, developmental, and neurobehavioral deficits have been reported in children born to women who were pregnant during the Yusho and Yu-Cheng incidents [Hsu et al. 2003; Hsu et al. 2005; Yang et al. 2005].

	Developmental delays were seen at all ages and were greater in children who were smaller and had neonatal signs of intoxication or nail deformities, or both. Follow-up testing indicated that effects on cognitive development persisted for several years after exposure [Guo et al. 1995]. In rhesus monkeys, exposure to PCBs is associated with alterations in the menstrual cycle, decreases in fertility, increases in spontaneous abortion, and a reduced number of conceptions [Arnold et al. 1990; Barsotti et al. 1976].
Key Points	• Reproductive function may be disrupted by exposure to PCBs. • Neurobehavioral and developmental deficits have been reported in newborns exposed to PCBs in utero.
Endocrine Effects	Limited but corroborative occupational data indicate a potential for toxic effects in the thyroid system in humans. Studies that have examined relationships between exposure to PCBs and thyroid hormone status have reported a variety of results. Findings include both negative and positive significant correlations between exposure to PCBs and circulating levels of thyroid-stimulating hormone (TSH), T4, or T3. These findings are dependent on the: • Specific type of analysis for exposure to PCBs, • Age of the cohort, and • Specific exposure scenario [Emmett et al. 1988; Koopman-Esseboom et al. 1994; Langer et al. 1998; Longnecker et al. 2003; Nagayama et al. 1998; Osius et al. 1999]. In a Dutch population, elevated levels of PCBs correlated with lower maternal levels of circulating triiodothyronine and total thyroxine and with higher plasma levels of TSH in infants during the second week and third month after birth. Infants exposed to higher levels of PCBs also had lower plasma levels of free

	thyroxine and total thyroxine in the second week after birth [Koopman-Esseboom et al. 1994]. In addition, a significantly elevated odds ratio for goiter was found among the Yu-Cheng cohort [Guo et al. 1999], suggesting the possibility of excessive thyroid disease in a population that experienced relatively high exposures to mixtures of PCBs and PCDFs. Thyroid hormones are essential for normal behavioral, intellectual, and neurologic development. Thus, the deficits in learning, memory, and attention processes among the offspring of women exposed to PCBs are partially or predominantly mediated by alterations in hormonal binding to the thyroid hormone receptor [ATSDR and EPA 1998]. Some PCB congeners are capable of competing with endogenous hormone for binding to this receptor, suggesting a possible mechanism of thyroid toxicity. Hydroxylated PCB metabolites appear to be particularly potent in this regard [ATSDR 2000]. Studies in animals, including rodents and primates, provide evidence of thyroid hormone involvement in PCB toxicity. The most convincing evidence that PCBs can exert toxicity by disrupting thyroid hormone system derives from two studies in rats [Cooke et al. 1996; Goldey et al. 1998]. The contribution of persistent organic pollutants (POPs) exposure to the incidence of diabetes has received little attention until recently. Recent studies in populations exposed to PCBs and chlorinated pesticides found a dose-dependent elevated risk of diabetes [Carpenter 2008].
Key Points	• The epidemiological studies suggest a link between exposure to PCBs and thyroid hormone toxicity in humans. • Studies in animals provide evidence of thyroid hormone involvement in the mechanism of PCB toxicity.
Hepatic Effects	Evidence for liver effects of occupational exposure to PCBs is essentially limited to elevation of serum liver

enzymes that are routinely examined in clinical assays. These serum liver enzymes include aspartate aminotransferase (AST), alanine aminotransferase (ALT), glutamyl transpeptidase (GGT) and other biochemical indices (e.g., bilirubin). No overt hepatotoxicity has been seen in workers exposed to PCBs [ATSDR 2000].

A cross-sectional survey found no significant differences in liver function test results between workers who manufacture capacitors with low-level chronic exposure and non-exposed controls [Fischbein et al. 1979]. However, in another cross-sectional study, liver function tests showed abnormalities that seemed to correlate with serum PCB levels [Maroni et al. 1981].

Increases in urinary excretion of porphyrins appear to be associated with occupational exposure to PCBs, an effect that is believed to be secondary to the induction of hepatic microsomal enzymes. Total bilirubin levels exhibit a positive correlation with serum PCB levels [Colombi et al. 1982; Maroni et al. 1984; Smith et al. 1982].

PCBs are more potent enzyme inducers than phenobarbital, a drug that occasionally causes clinical problems due to its microsomal enzyme-inducing effects. The health implications of enzyme induction include the occurrence of disease secondary to increased metabolism of endogenous or exogenous substances and interference in medical therapy due to increased metabolism of administered drugs. The enzyme-inducing effects of PCBs can persist long after cessation of exposure [Letz 1983].

In the Yu-Cheng population, the incidence of chronic liver disease and cirrhosis was significantly higher than the incidence of these conditions in the general population of Taiwan. Asymptomatic hepatomegaly has been reported in exposed workers, many of whom had concomitant elevated serum PCB levels. Due to the mixed chemical nature of the exposure, the results cannot be attributed solely to PCBs [ATSDR 2000].

	Liver damage is a consistent and prominent finding among animals exposed to PCBs, particularly rats and monkeys, which are the species tested most extensively. Liver effects are similar in nature among species and appear to be reversible when mild. Liver effects characteristically include • Fat deposition, • Fibrosis, • Hepatic microsomal enzyme induction, • Increased serum levels of liver-related enzymes indicative of possible hepatocellular damages, • Liver enlargement, and • Necrosis [ATSDR 2000].
Key Points	• Although liver damage is common in animals exposed to PCBs, overt hepatotoxicity is uncommon in humans. • Exposure to PCBs can increase serum levels of hepatic enzymes and can induce microsomal enzyme function.
Carcinogenic Effects	Epidemiologic studies have raised concerns about the potential carcinogenicity of PCBs. A retrospective analysis of a study of two plants that manufactured electrical capacitors in the United States found a significant increase in the incidence of cancer. The primary target tissues for the cancers were the liver, gallbladder, and biliary tract [Brown 1987]. Likewise, an increased incidence of melanomas associated with exposure to PCBs has also been observed for workers who manufactured capacitors [Bahn et al. 1976; Ruder et al. 2006; Sinks et al. 1992]. Sinks et al. [1992] observed the increased risks for brain cancer among workers exposed to PCBs in an electrical capacitor manufacturing plant in Indiana, and this finding has been further confirmed by a recent study from Ruder et al. [2006]. One study suggests that exposure to electrical insulating fluids, for which the main constituent is PCBs, may

cause malignant melanoma of the skin [Loomis et al. 1997].

The results of a mortality study of workers employed between 1944 and 1977 at an electrical capacitor manufacturing plant were recently reported. The report pointed out that PCBs alone or in combination with other chemicals could be associated with increased risks for

- Liver or biliary,
- Stomach, intestinal, and
- Thyroid cancers [Mallin et al. 2004].

A recent analysis of a cohort of 24,865 capacitor-manufacturing workers exposed to PCBs at three plants showed evidence of associations between cumulative exposure to PCBs and increased total cancer and intestinal cancer mortality among female long-term workers and excess myeloma for male long-term workers [Ruder et al. 2014].

In contrast, increased cancer incidence was not observed in male workers who manufactured capacitors in Sweden exposed to PCBs for an average of 6.5 years [Gustavsson et al. 1986]. The results from the Swedish study, however, cannot rule out the possibility of a carcinogenic risk from PCB exposure because of the small size of the cohort and relatively brief follow-up period.

Different mixtures of PCBs had different potencies and, thus, different toxicity. As noted previously, PCB mixtures found in the environment are different from commercial PCB mixtures. EPA agreed that some mixtures of PCBs are more likely to cause cancer than others, and found that all PCBs mixtures can cause cancer [Cogliano 1998; EPA 1996c].

In environmental case-control studies that compared PCB concentrations in breast tissue in both women with (case patients) and without (case controls) breast cancer, some studies reported higher levels of total PCBs among case patients than control patients [Falck et al. 1992; Guttes et al. 1998; Wassermann et al.

1976]. Other studies found no elevated PCB levels in breast tissue in patients with breast cancer [Aronson et al. 2000; Liljegren et al. 1998; Unger et al. 1984]. A recent occupational cohort study found no overall elevation in breast cancer risk after occupational exposure to PCBs [Silver et al. 2009].

In persons without known occupational exposure to PCBs, elevations of PCB level in the adipose tissue and serum have been associated with an increased risk of non-Hodgkin lymphoma (NHL) [De Roos et al. 2005; Engel et al. 2007; Hardell E et al. 2001; Hardell L et al. 1996; Rothman et al. 1997].

After registering as Yusho victims, 887 male and 874 female patients were observed for an average 11 years. A retrospective study found statistically significant increased liver cancer mortality rates among the males compared to national liver cancer mortality rates [Kuratsune et al. 1987].

A retrospective mortality study of 1940 Yu-Cheng cases found no statistically significant increased mortality from liver and intrahepatic bile duct cancers [Hsieh et al. 1996].

Before the comprehensive study conducted by Mayes et al. [1998], only commercial mixtures 60□ chlorinated had been tested, and controversy existed about whether mixtures with lower chlorine content were carcinogenic. The Mayes et al. study [Mayes et al. 1998] supported the position that all PCB mixtures can cause cancer. Data from animal studies have shown that PCBs cause gastrointestinal tract tumors, hepatocarcinomas, leukemia, lymphomas, and pituitary tumors [ATSDR 2000].

On the basis of these laboratory data, EPA has determined that PCBs are probable human carcinogens and has assigned them the cancer weight-of-evidence classification B2 [IRIS 2012]. DHHS concluded that PCBs are reasonably anticipated to be carcinogenic in humans based on sufficient evidence of carcinogenicity

	in animals [NTP 2011]. In February 2013, 26 experts from 12 countries met at the International Agency for Research on Cancer (IARC), Lyon, France, to reassess the carcinogenicity of PCBs. The Working Group considered more than 70 independent epidemiological studies with informative data for carcinogenicity of PCBs in human beings. On the basis of sufficient evidence of carcinogenicity in humans and experimental animals, the IARC classified PCBs as carcinogenic to humans (Group 1). The classification is based on consistent association between exposure to PCBs and increased risk of melanoma in humans [IARC 2013].
Key Points	• On the basis of data from animal studies, DHHS and EPA consider PCBs a probable human carcinogen. • On the basis of sufficient evidence of carcinogenicity in humans and experimental animals, the IARC classified PCBs as carcinogenic to humans (Group 1).
Other Effects	Occupational and epidemiologic studies have suggested or demonstrated other adverse health effects from exposure to PCBs. These health effects can involve the: • Cardiovascular, • Gastrointestinal, • Immune, • Musculoskeletal, and • Neurological systems. In southwest Quebec, adults who ate fish from PCB-contaminated waters had • Significantly greater motor retardation, • Poorer results on certain memory and attention tests, and • Higher scores on a standardized confusion scale than did control adults.

	These neurological deficits were directly related to the frequency of fish consumption [Mergler et al. 1998]. Immune system effects reported in PCB-exposed populations include alterations in the ratio of helper to killer (CD4 CD8) T-cells, decreases in IgA and IgM antibody levels, decreases in monocyte and granulocyte counts, and decreases in natural killer cell count [Svensson et al. 1994]. In the Yusho and Yu-Cheng populations, the immunosuppressive effects of PCB exposure were associated with an increased incidence of persistent respiratory infection and enhanced responsiveness to mitogens [Guo et al. 1995]. Appetite loss has been reported in transformer and electrical equipment manufacturing workers exposed to various PCB-containing mixtures. Other nonspecific gastrointestinal symptoms experienced by workers exposed to PCBs include nausea, epigastric distress and pain, and intolerance to fatty foods [Emmett et al. 1988; Smith et al. 1982]. A recent study has indicated that several PCB metabolites induce gene mutations, chromosome breaks, chromosome loss and polyploidization in cells in culture and even provided the first evidence that a PCB congener is mutagenic in vivo [Robertson and Ludewig 2011].
Key Points	• Additional adverse effects of PCBs may involve the o Cardiovascular, o Gastrointestinal, o Genetic systems, o Immune, o Musculoskeletal, and o Neurological systems.

Progress Check

7. Adverse dermal effects have been reported in the following subjects **EXCEPT**

   A. Workers occupationally exposed to PCBs.
   B. Those in the general population who consume large amounts of fish contaminated with PCBs and other environmentally persistent chemicals.
   C. Victims of the Yusho (Japan) and Yu-Cheng (Taiwan) poisoning episodes exposed to PCBs and their heat-degradation products.
   D. Monkeys after long-term oral exposure to commercial mixtures of PCBs.

   To identify relevant content, see "Dermal Effects" in this section.

8. Which of the following statements about the potential carcinogenicity of PCBs is considered **INCORRECT**?

   A. Potential human health effects from exposure to mixtures of PCBs do not include cancer.
   B. Some mixtures of PCBs are more likely to cause cancer than others.
   C. Exposure to PCBs has been associated with increased incidence of some cancers.
   D. Data from animal studies have shown clearly that PCBs cause different kinds of tumors.

   To identify relevant content, see "Carcinogenic Effects" in this section.

9. Additional adverse effects of PCBs may include which of the following?

   A. Liver damage.
   B. Neurobehavioral and developmental deficits.
   C. Thyroid hormone anomalies.
   D. All of the above.

   To identify relevant content, see "Other Effects" in this section.

Clinical Assessment

Learning Objective	Upon completion of this section, you will be able to • Describe characteristic findings on clinical assessment of patients exposed to PCBs, and • Describe a rational approach for evaluating a patient with a history of occupational or environmental exposure, or both, to PCBs.
Introduction	Patients who have been exposed to PCBs often are undergoing clinical assessment long after their last exposure occurred (possibly years). The ability to extrapolate peak blood levels is problematic in these cases. PCBs have low acute toxicity but are of public health concern because they persist in the environment, bioaccumulate in human and animal tissues, and potentially can cause chronic or delayed toxicity. Documenting an adequate occupational and environmental exposure history in addition to a physical examination is essential for identifying health effects related to PCBs. Identifying cases of chloracne may be helpful, but the absence of chloracne would not rule out significant exposure.
Patient History and Physical Examination	A detailed history will facilitate the diagnosis of chronic PCB poisoning. Pertinent information includes occupational histories of all household members and history of the patient□s sport and subsistence fish consumption. Because PCBs are hepatotoxins, history of exposure to other potentially hepatotoxic agents, such as ethanol intake and medications with known hepatotoxicity, should be obtained. During the physical examination, physicians should pay particular attention to the skin and hepatic systems. Encountering a patient with PCB toxicity should trigger consideration of whether this is a sentinel event,

	indicating the possibility of other similarly exposed persons such as co-workers or family members.
Signs and Symptoms-Acute Exposure	**Acute exposure** PCBs have very low potential for producing acute toxic effects. The only overt sign of exposure to PCBs is chloracne, which is a specific skin lesion. Although chloracne may resemble typical adolescent acne, it has certain distinct features [Crow 1970; Letz 1983]. • Chloracne's most distinctive feature is cystic, skin colored lesions that measure 1–10 mm. • Chloracne's other prominent feature is comedonal lesions. The comedones and cysts can become inflamed and secondarily infected with large pustules. Unlike adolescent acne, chloracne may occur at any age and may involve the arms, back, face, legs, neck, and trunk. Chloracne can be very persistent and refractory to treatment. Acneiform lesions do not appear in all severely exposed patients, so the absence of chloracne does not rule out exposure. New cases of chloracne should be reported to the local or state health department. Other acute effects that may be seen include eye irritation, nausea, and vomiting [LaDou 2006]. Elevated liver enzymes are the most sensitive indicator of exposure to PCBs in animals, and alterations in • AST (SGOT), • GGT (GGTP), • Bilirubin, and • Albumin levels have been reported in human epidemiologic studies.

	The absence of alterations in these liver function markers does not rule out excessive exposure to PCBs. The presence of specific signs, symptoms, or laboratory abnormalities, with the possible exception of chloracne, is difficult to relate to exposure to PCBs absolutely in any given patient. A practical approach for the routine work-up of individual patients potentially exposed to PCBs would be to do the following: • Take a through occupational and environmental exposure history, • Examine the skin, • Order baseline liver function tests, and • If indicated, perform subsequent testing limited to patients with clinical problems or history of extensive exposure such as an accidental spill or a capacitor rupture that caused heavy skin contamination [Letz 1983]. This clinical approach may be used for monitoring electrical utility workers or other persons with some potential for ongoing occupational exposure. Serum PCB level is a useful indicator of a patient□s exposure. Serum PCB tests are readily available at most commercial reference laboratories. However, serum PCB levels may not be consistent with adverse health effects. [Roseman 2005].
Signs and Symptoms-Chronic Exposure	**Chronic exposure** Many people who are chronically exposed to PCBs exhibit no overt signs or symptoms of toxicity. Among persons with hepatic involvement, signs of exposure to PCBs can include • Abdominal pain, • Anorexia, • Jaundice, • Nausea, • Vomiting, • Weight loss, and

	• Uroporphyria. Headache, dizziness, and edema have also been reported (see earlier section on Adverse Health Effects for more detail).
Differential Diagnosis	Occupational exposure to PCBs may be accompanied by exposure to chlorinated dibenzodioxin and dibenzofuran contaminants, which are much more toxic than PCBs in comparative animal studies. These substances can cause chronic fatigue and elevated liver enzymes. Mild chloracne should not be confused with other rashes (e.g., acne, seborrheic keratitis, keratoma). A skin biopsy of lesions may help establish the diagnosis [LaDou 2006].
Medical Surveillance	Workers intermittently exposed to PCBs should have a baseline skin examination and liver function tests. Follow-up examination can be limited to symptomatic persons and workers exposed as a consequence of accidental contamination. For persons with signs and symptoms consistent with high exposures to PCBs (e.g., chloracne, elevated AST and ALT), a serum PCB level should be obtained to confirm exposure.
Key Points	• Chloracne is the only known overt sign of PCB toxicity; however, the absence of chloracne does not rule out exposure. • Signs of low level, chronic exposure to PCBs are generally subtle, if present at all.
Progress Check	10. Which of the following should be included in the clinical evaluation of a patient with a history of exposure to PCBs? A. A thorough occupational and environmental exposure history. B. A thorough skin examination. C. Liver function tests. D. All of the above. *To review relevant content, see "Patient History and Physical Examinations" in this section.*

11. PCB exposure may manifest clinically as which of the following?

    A. Acne vulgaris.
    B. Chloracne.
    C. Parkinsonism.
    D. Acute tubular necrosis.

    To review relevant content, see "Signs and Symptoms – Acute Exposure" and "Signs and Symptoms – Chronic Exposure" in this section.

Clinical Assessment - Laboratory Tests

Learning Objective	Upon completion of this section, you will be able to • Describe measurements that can help diagnose exposure to PCBs.
Introduction	The lipophilic nature of PCBs causes them to accumulate in fat; consequently, analyzing biopsied adipose tissue has been used to measure long-term exposure. Serum PCB analysis is less invasive than tissue biopsy, and it can be performed by most commercial reference laboratories. Although such tests are useful for gauging exposure, they may not be consistent with adverse health effects. Select laboratories have the capability to perform PCB analyses on human tissue. Testing human tissue for PCB content, however, remains principally a research tool.
Direct Biologic Indicators	PCBs have been detected in the blood, adipose tissue, and breast milk of non-occupationally exposed members of the general population [CDC 2009; EPA 1986b; Greizerstein et al. 1999; Gunderson and Gunderson 1995; Patterson et al. 2008]. Since the United States stopped making PCB compounds, body burdens of PCBs in humans have decreased. This decrease is evidenced by lower PCB levels reported in human adipose tissue, blood serum, and breast milk [Anderson et al. 1998;

Fensterheim 1993; Hanrahan et al. 1999; Lunden et al. 1998; Schade et al. 1998].

PCB compounds generally can be found at the parts per trillion (ppt) levels in the lipid stores of humans, especially persons living in industrialized societies. The general population is exposed to PCB compounds primarily by ingesting high-fat foods, such as

- Dairy products,
- Eggs,
- Animal fats, and
- Some fish and wildlife [CDC 2009; Patterson et al. 2008].

However, no specified PCB values are deemed normal or toxic levels.

Some researchers believe that PCB levels in the serum and tissue provide a reliable measurement of long-term exposure. PCB levels in the serum and tissue can be measured by many laboratories although analyses results may not be consistent with health effects.

A correlation between increasing levels of serum PCBs and dermatologic findings, including chloracne, has not been found consistently in human epidemiologic studies. However, statistically significant associations between dermatologic effects and plasma levels of higher chlorinated PCB congeners have been reported [Fischbein et al. 1982; Fischbein et al. 1979; Smith et al. 1982].

Although PCBs accumulate in breast milk, the American Association of Pediatrics (AAP) has concluded that the risks posed by PCBs in breast milk are outweighed by the benefits of breastfeeding in all but the most unusual circumstances. Therefore, AAP does not recommend that breast milk be tested for PCBs because the test results would not likely change the recommendation to breast feed. Additionally, AAP recommends consulting local health department officials who are aware of the PCB

	problems in unusual circumstances or where high exposures have occurred [AAP 2003].
Indirect Biologic Indicators	Liver function tests are nonspecific. The combination of asymptomatic hepatomegaly and mild, nonspecific elevations of hepatic enzymes suggests a chronic inflammatory liver process or hepatitis. Hepatitis can be • Drug-induced, • Genetic, • Infectious, • Toxic, • Caused by ethanol ingestion, or • Associated with connective tissue disease. The major cause of liver disease in the United States is ethanol ingestion. Less common causes are environmental exposures, resulting in either acute or chronic toxic hepatitis. Infectious hepatitis includes disease caused by viruses such as A, B, C, and other possible agents of non-A, non-B hepatitis. Hepatitis can also occur with Epstein-Barr virus and cytomegalovirus infections. Some connective tissue diseases such as lupus erythematosus are associated with a specific type of hepatitis. Infiltrative diseases such as sarcoidosis or amyloidosis, and rare genetic diseases such as Wilson disease, primary hemochromatosis, and alpha-1-antitrypsin deficiency, must be excluded. Normal liver enzyme values do not rule out significant PCB exposure; body burden still might be elevated. To help arrive at a diagnosis, viral serology and a heterophil antibody test should be considered. If the

	patient has suggestive signs or symptoms, a serum iron and total iron binding capacity, serum copper and ceruloplasmin, and antinuclear antibodies might help with the diagnosis. Assays for suspected hepatotoxins might also be useful. If other tests do not provide sufficient information, further evaluation might include ultrasound and percutaneous liver biopsy.
Key Points	• Serum or adipose tissue PCB levels can indicate exposure, but they are difficult to interpret clinically. • AAP does not recommend testing breast milk for PCBs, and encourages breastfeeding in all but the most unusual circumstances. • Elevated hepatic enzyme levels are of limited value in diagnosing exposure to PCBs.

Progress Check	12. Which of the following statements is true? A. Testing PCB serum level is expensive and not readily available, but correlates well with health risk. B. AAP recommends that breast milk be tested for PCBs because human milk contains a steroid that inhibits PCB metabolism and excretion. C. The toxic serum PCB value is 20 ppb. D. None of the above. *To review relevant content, see "Direct Biologic Indicators" in this section.*

How Should Patients Exposed to PCBs Be Treated and Managed?

Learning Objectives	Upon completion of this section, you will be able to • Describe the principal treatment strategy for managing PCB poisoning and • Describe the measures for preventing occupational and environmental exposure to PCBs.
Introduction	No specific treatment exists for PCB accumulation. Patients should avoid further PCB exposure and also avoid other hepatotoxic substances, including ethanol.

Acute Exposure	Treat acute skin and eye PCB exposure immediately by flushing with copious amounts of water. However, post-contamination washing cannot ensure removal of all contamination [Wester et al. 1983]. Remove contaminated clothing and discard properly. Carefully observe patients with inhalation exposure for any systemic signs or symptoms of toxicity and administer treatment as necessary. No specific measures are available to reduce respiratory tract absorption. In the rare event of ingestion of PCBs, emesis would be contraindicated because of the high risk of aspiration. The value of administering activated charcoal after ingestion is unknown. Unless a patient has an intact or protected airway, administering charcoal is contraindicated [Alaspaa et al. 2005; Chyka et al. 2005]. Exposed persons should have periodic follow-up examinations with particular attention to hepatic function and dermal lesions.
Key Points	• No antidote exists for PCB exposure; therefore, treatment is supportive.
Chronic Exposure	No specific treatment is available for chronic PCB toxicity. Because no known methods exist for reducing the reserves of PCBs in adipose tissues, purging the body of PCBs should not be attempted. Initial treatment of chloracne is based on • Cessation of PCB exposure, • Good skin hygiene, and • Dermatologic measures commonly used for acne vulgaris. Given the difficulty in treating chloracne, the patient should be referred to a dermatologist. If chronic exposure has occurred due to consuming contaminated fish or game, the patient should be

informed that PCBs tend to accumulate in the body with continued exposure, and counseled about the importance of minimizing further exposure.

In areas with a known PCB problem, state and local public health or natural resources departments typically issue advisories. These advisories specify the waters or hunting areas where PCB-contaminated fish and game likely are, and list the species and size of fish or game that are of concern. Such advisories might completely ban consumption, or might recommend limits on the frequency with which certain species are to be consumed. To minimize the risk for further exposure, sport and subsistence fishers are encouraged to familiarize themselves with and observe advisory recommendations [ATSDR 2000].

Patients should be monitored for increased hepatic enzymes. Because PCBs are hepatotoxins, history of exposure to other potentially hepatotoxic agents should be obtained. To minimize the risk of hepatic damage, patients should be encouraged to avoid exposure to other hepatotoxins, including medications with known hepatotoxicity, ethanol, and chlorinated solvents.

The carcinogenic potential and other risks from exposure to PCBs should be carefully reviewed with the patient.

AAP encourages breastfeeding in all but the most unusual circumstances [AAP 2003].

Prevention in the Workplace	**Work Practices** The following measures [LaDou 2006] may be adopted at work to avoid exposure to PCBs. • Eliminate PCBs from the workplace or implement engineering changes to isolate the PCBs. If neither of these approaches is feasible, then use special PCB-resistant gloves and protective clothing. • Maintain adequate ventilation during spill cleanup or maintenance of vessels containing PCBs. If this is not possible, provide approved respirators. • Make provisions for proper decontamination or disposal of contaminated clothing or equipment. • Post clearly the locations where PCBs are stored as required by law. • Conduct environmental sampling as necessary to ensure adequate worker protection or safety for public reentry to contaminated areas. • Establish reentry or cleanup levels for dioxins and PCBs to protect workers who reoccupy buildings after a PCB fire. • Record health complaints of any type. **Medical Surveillance** Workers intermittently exposed to PCBs should have a baseline skin examination and liver function tests. For workers with signs and symptoms consistent with large exposures to PCBs (e.g., chloracne, elevated AST and ALT), obtain confirmation of exposure to determine serum PCB level.
Prevention at Home	**Home Practices** • Open all windows and use fans in your workspace when maintaining or repairing any products containing PCBs. • Wear a respirator or protective gloves, or both. • You and your children may be exposed to PCBs by eating fish or wildlife caught from contaminated locations. Certain states, Native American tribes, and U.S. territories have issued advisories to warn people about PCB-contaminated fish and fish-eating

	wildlife. You can reduce your family's exposure to PCBs by following these advisories.
Key Points	• The goal of treating chronically exposed patients is preventing any additional exposure to PCBs. • Exposure to PCBs at work or home is avoidable if the proper preventive measures are adopted.
Progress Check	13. Which of the following statements regarding treatment for chronic PCB toxicity is **NOT CORRECT**? A. The goal in treating chronically exposed patients is preventing any additional exposure to PCBs. B. No specific treatment is available for chronic PCB toxicity. C. Breastfeeding should be avoided. D. No known methods exist for reducing the burdens of PCBs in human tissues. *To review relevant content, see "Chronic Exposure" in this section.* 14. All of the following preventive measures to avoid PCB exposure at work or home are true **EXCEPT** A. Use special PCB-resistant gloves and protective clothing. B. Maintain adequate ventilation during spill cleanup or maintenance of vessels containing PCBs. If this is not possible, provide masks. C. Certain states, Native American tribes, and U.S. territories have issued advisories to warn people about PCB-contaminated fish and fish-eating wildlife. You can reduce your family's exposure to PCBs by obeying these advisories. D. Locations where PCBs are stored should be clearly posted as required by law. *To review relevant content, see "Prevention at Home" and "Prevention in the Workplace" in this section.*

What Instructions Should Be Given to Patients Exposed to PCBs?

Learning Objective	Upon completion of this section, you will be able to • Describe appropriate instructions for patients exposed to PCBs.
Introduction	All patients exposed to PCBs need basic guidance on • Self-care, so they can minimize further risks and avoid complications to the extent possible, and • Clinical follow-up, so they understand when and why to return for further medical attention. ATSDR has developed a patient education sheet on PCBs that you might find useful. It can be found at http: www.atsdr.cdc.gov csem pcb docs pcb patient education.pdf
Self-care Guidance for Patients	Patients should be advised to avoid exposures and conditions that might further increase their risk of disease or worsen their existing condition. **At Work** • Eliminate PCBs from the workplace, or implement engineering changes to isolate the PCBs. If neither of these approaches is feasible, use special PCB-resistant gloves and protective clothing. • Maintain adequate ventilation during spill cleanup or maintenance of vessels containing PCBs. If this is not possible, provide approved respirators. • Make provisions for proper decontamination or disposal of contaminated clothing or equipment. • Dispose of existing PCBs through appropriate toxic waste facilities. • Conduct environmental sampling as necessary to ensure adequate worker protection or safety for public reentry to contaminated areas. • Establish reentry or cleanup levels for dioxins and PCBs to protect workers who reoccupy buildings after a PCB fire.

	• Report persistent health effects (e.g., unexplained weight loss, muscle pain, frequent coughing, and sleep problems). These symptoms may be due to stress or recall bias and may not be specifically linked to the toxic effects of PCBs. **At Home** • Open all windows and use fans in your workspace when conducting maintenance or repairing any products containing PCBs. • If ventilation is poor, wear a respirator and protective gloves. • Seek medical attention immediately if an acute exposure occurs. • Lower exposure to PCBs by looking for and following health advisories issued by states, Native American tribes, or U.S. territories when eating fish or wildlife caught from locations contaminated with PCBs.
Clinical Follow- up Guidance for Patients	PCBs have been implicated as a potential cause of cancer in humans. Screening tests are available for breast cancer and melanoma. If patients believe that they are being exposed to PCBs, advise them how to stop the exposure. Also tell them how to contact worksite or environmental regulatory agencies that will assess exposure risks and prescribe protective actions. Advise patients with suspected or confirmed historic exposure to PCBs to be seen by you or their primary care provider periodically and monitored for signs of disease and changes in health status. Advise patients to consult their physicians if they develop signs or symptoms of PCB exposure such as • Appetite loss, • Joint pain, • Nausea, • Skin disorders, changes, or discoloration, • Breast changes or lumps, and or • Stomach distress and pain.

	ATSDR patient education sheet on PCBs includes a more detailed checklist that you can use to indicate which types of follow up are relevant for a given patient.
Key Points	• Advise patients to avoid PCB exposures and conditions that might further increase their risk of disease or worsen their existing condition. • Advise patients to contact their physicians if they develop skin problems or other health changes.
Progress Check	15. Patients who have been exposed to PCBs should be advised to A. Speak to their employers about reducing workplace exposures (if exposures are occupational). B. Learn how to avoid further exposure. C. Know when to call their doctors. D. All of the above. *To review relevant content, see all topics in this section.*

IARC MONOGRAPHS ON THE EVALUATION OF CARCINOGENIC RISKS TO HUMANS

International Agency for Research on Cancer

World Health Organization

IARC MONOGRAPHS

In 1969, the International Agency for Research on Cancer (IARC) initiated a programme on the evaluation of the carcinogenic risk of chemicals to humans involving the production of critically evaluated monographs on individual chemicals. The programme was subsequently expanded to include evaluations of carcinogenic risks associated with exposures to complex mixtures, lifestyle factors and biological and physical agents, as well as those in specific occupations. The objective of the programme is to elaborate and publish in the form of monographs critical reviews of data on carcinogenicity for agents to which humans are known to be exposed and on specific exposure situations; to evaluate these data in terms of human risk with the help of international working groups of experts in carcinogenesis and related fields; and to indicate where additional research efforts are needed. The lists of IARC evaluations are regularly updated and are available on the Internet at http://monographs.iarc.fr/.

This programme has been supported since 1982 by Cooperative Agreement U01 CA33193 with the United States National Cancer Institute, Department of Health and Human Services. Additional support has been provided since 1986 by the European Commission Directorate-General for Employment, Social Affairs, and Inclusion, initially by the Unit of Health, Safety and Hygiene at Work, and since 2014 by the European Union Programme for Employment and Social Innovation "EaSI" (2014–2020) (for further information please consult: http://ec.europa.eu/social/easi). Support has also been provided since 1992 by the United States National Institute of Environmental Health Sciences, Department of Health and Human Services. The contents of this volume are solely the responsibility of the Working Group and do not necessarily represent the official views of the United States National Cancer Institute, the United States National Institute of Environmental Health Sciences, the United States Department of Health and Human Services, or the European Commission.

CONTENTS

NOTE TO THE READER

The term 'carcinogenic risk' in the *IARC Monographs* series is taken to mean that an agent is capable of causing cancer. The *Monographs* evaluate cancer hazards, despite the historical presence of the word 'risks' in the title.

Inclusion of an agent in the *Monographs* does not imply that it is a carcinogen, only that the published data have been examined. Equally, the fact that an agent has not yet been evaluated in a *Monograph* does not mean that it is not carcinogenic. Similarly, identification of cancer sites with *sufficient evidence* or *limited evidence* in humans should not be viewed as precluding the possibility that an agent may cause cancer at other sites.

The evaluations of carcinogenic risk are made by international working groups of independent scientists and are qualitative in nature. No recommendation is given for regulation or legislation.

Anyone who is aware of published data that may alter the evaluation of the carcinogenic risk of an agent to humans is encouraged to make this information available to the Section of IARC Monographs, International Agency for Research on Cancer, 150 cours Albert Thomas, 69372 Lyon Cedex 08, France, in order that the agent may be considered for re-evaluation by a future Working Group.

Although every effort is made to prepare the *Monographs* as accurately as possible, mistakes may occur. Readers are requested to communicate any errors to the Section of IARC Monographs, so that corrections can be reported in future volumes.

LIST OF PARTICIPANTS

Members[1]

Antonio Agudo

Cancer Epidemiology Research Program
Catalan Institute of Oncology
Barcelona

[1] Working Group Members and Invited Specialists serve in their individual capacities as scientists and not as representatives of their government or any organization with which they are affiliated. Affiliations are provided for identification purposes only. Invited Specialists do not serve as Meeting Chair or Subgroup Chair, draft text that pertains to the description or interpretation of cancer data, or participate in the evaluations.

Each participant was asked to disclose pertinent research, employment, and financial interests. Current financial interests and research and employment interests during the past 4 years or anticipated in the future are identified here. Minor pertinent interests are not listed and include stock valued at no more than US $1000 overall, grants that provide no more than 5% of the research budget of the expert's organization and that do not support the expert's research or position, and consulting or speaking on matters not before a court or government agency that does not exceed 2% of total professional time or compensation. All grants that support the expert's research or position and all consulting or speaking on behalf of an interested party on matters before a court or government agency are listed as significant pertinent interests.

[4] Each Observer agreed to respect the Guidelines for Observers at IARC Monographs meetings. Observers did not serve as Meeting Chair or Subgroup Chair, draft any part of a Monograph, or participate in the evaluations. They also agreed not to contact participants before the meeting, not to lobby them at any time, not to send them written materials, and not to offer them meals or other favours. IARC asked and reminded Working Group Members to report any contact or attempt to influence that they may have encountered, either before or during the meeting.
[5] Erik Carlson is employed by General Electric Company as a toxicologist and works on PCB-related issues. He has provided expert opinion and testimony in the context of regulatory and legislative process and he holds stocks and bonds from stakeholders.
[6] John Schell has consulted for several companies on PCB-related issues and provided expert opinions on regulatory issues related to PCBs.

PREAMBLE

The Preamble to the *IARC Monographs* describes the objective and scope of the programme, the scientific principles and procedures used in developing a *Monograph*, the types of evidence considered and the scientific criteria that guide the evaluations. The Preamble should be consulted when reading a *Monograph* or list of evaluations.

A. GENERAL PRINCIPLES AND PROCEDURES

1. Background

Soon after IARC was established in 1965, it received frequent requests for advice on the carcinogenic risk of chemicals, including requests for lists of known and suspected human carcinogens. It was clear that it would not be a simple task to summarize adequately the complexity of the information that was available, and IARC began to consider means of obtaining international expert opinion on this topic. In 1970, the IARC Advisory Committee on Environmental Carcinogenesis recommended '...that a compendium on carcinogenic chemicals be prepared by experts. The biological activity and evaluation of practical importance to public health should be referenced and documented.' The IARC Governing Council adopted a resolution concerning the role of IARC in providing government authorities with expert, independent, scientific opinion on environmental carcinogenesis. As one means to that end, the Governing Council recommended that IARC should prepare monographs on the evaluation of carcinogenic risk of chemicals to man, which became the initial title of the series.

In the succeeding years, the scope of the programme broadened as *Monographs* were developed for groups of related chemicals, complex mixtures, occupational exposures, physical and biological agents and lifestyle factors. In 1988, the phrase 'of chemicals' was dropped from the title, which assumed its present form, *IARC Monographs on the Evaluation of Carcinogenic Risks to Humans*.

Through the *Monographs* programme, IARC seeks to identify the causes of human cancer. This is the first step in cancer prevention, which is needed as much today as when IARC was established. The global burden of cancer is high and continues to increase: the annual number of new cases was estimated at 10.1 million in 2000 and is expected to reach 15 million by 2020 (Stewart & Kleihues, 2003). With current trends in demographics and exposure, the cancer burden has been shifting from high-resource countries to low- and medium-resource countries. As a result of *Monographs* evaluations, national health agencies have been able, on scientific grounds, to take measures to reduce human exposure to carcinogens in the workplace and in the environment.

The criteria established in 1971 to evaluate carcinogenic risks to humans were adopted by the Working Groups whose deliberations resulted in the first 16 volumes of the *Monographs* series. Those criteria were subsequently updated by further ad hoc Advisory Groups (IARC, 1977, 1978, 1979, 1982, 1983, 1987, 1988, 1991; Vainio *et al.*, 1992; IARC, 2005, 2006).

The Preamble is primarily a statement of scientific principles, rather than a specification of working procedures. The procedures through which a Working Group implements these principles are not specified in detail. They usually involve operations that have been established as being effective during previous *Monograph* meetings but remain, predominantly, the prerogative of each individual Working Group.

2. Objective and scope

The objective of the programme is to prepare, with the help of international Working Groups of experts, and to publish in the form of *Monographs*, critical reviews and evaluations of evidence on the carcinogenicity of a wide range of human exposures. The *Monographs* represent the first step in carcinogen risk assessment, which involves examination of all relevant information to assess the strength of the available evidence that an agent could alter the age-specific incidence of cancer in humans. The *Monographs* may also indicate where additional research efforts are needed, specifically when data immediately relevant to an evaluation are not available.

In this Preamble, the term 'agent' refers to any entity or circumstance that is subject to evaluation in a *Monograph*. As the scope of the programme has broadened, categories of agents now include specific chemicals, groups of related chemicals, complex mixtures, occupational or environmental exposures, cultural or behavioural practices, biological organisms and physical agents. This list of categories may expand as causation of, and susceptibility to, malignant disease become more fully understood.

A cancer 'hazard' is an agent that is capable of causing cancer under some circumstances, while a cancer 'risk' is an estimate of the carcinogenic effects expected from exposure to a cancer hazard. The *Monographs* are an exercise in evaluating cancer hazards, despite the historical presence of the word 'risks' in the title. The distinction between hazard and risk is important, and the *Monographs* identify cancer hazards even when risks are very low at current exposure levels, because new uses or unforeseen exposures could engender risks that are significantly higher.

In the *Monographs*, an agent is termed 'carcinogenic' if it is capable of increasing the incidence of malignant neoplasms, reducing their latency, or increasing their severity or multiplicity. The induction of benign neoplasms may in some circumstances (see Part B, Section 3a) contribute to the judgement that the agent is carcinogenic. The terms 'neoplasm' and 'tumour' are used interchangeably.

The Preamble continues the previous usage of the phrase 'strength of evidence' as a matter of historical continuity, although it should be understood that *Monographs* evaluations consider studies that support a finding of a cancer hazard as well as studies that do not.

Some epidemiological and experimental studies indicate that different agents may act at different stages in the carcinogenic process, and several different mechanisms may be involved. The aim of the *Monographs* has been, from their inception, to evaluate evidence of carcinogenicity at any stage in the carcinogenesis process, independently of the underlying mechanisms. Information on mechanisms may, however, be used in making the overall evaluation (IARC, 1991; Vainio *et al.*, 1992; IARC, 2005, 2006; see also Part B, Sections 4 and 6). As mechanisms of carcinogenesis are elucidated, IARC convenes international scientific conferences to determine whether a broad-based consensus has emerged

on how specific mechanistic data can be used in an evaluation of human carcinogenicity. The results of such conferences are reported in IARC Scientific Publications, which, as long as they still reflect the current state of scientific knowledge, may guide subsequent Working Groups.

Although the *Monographs* have emphasized hazard identification, important issues may also involve dose–response assessment. In many cases, the same epidemiological and experimental studies used to evaluate a cancer hazard can also be used to estimate a dose–response relationship. A *Monograph* may undertake to estimate dose–response relationships within the range of the available epidemiological data, or it may compare the dose–response information from experimental and epidemiological studies. In some cases, a subsequent publication may be prepared by a separate Working Group with expertise in quantitative dose–response assessment.

The *Monographs* are used by national and international authorities to make risk assessments, formulate decisions concerning preventive measures, provide effective cancer control programmes and decide among alternative options for public health decisions. The evaluations of IARC Working Groups are scientific, qualitative judgements on the evidence for or against carcinogenicity provided by the available data. These evaluations represent only one part of the body of information on which public health decisions may be based. Public health options vary from one situation to another and from country to country and relate to many factors, including different socioeconomic and national priorities. Therefore, no recommendation is given with regard to regulation or legislation, which are the responsibility of individual governments or other international organizations.

3. Selection of agents for review

Agents are selected for review on the basis of two main criteria: (a) there is evidence of human exposure and (b) there is some evidence or suspicion of carcinogenicity. Mixed exposures may occur in occupational and environmental settings and as a result of individual and cultural habits (such as tobacco smoking and dietary practices). Chemical analogues and compounds with biological or physical characteristics similar to those of suspected carcinogens may also be considered, even in the absence of data on a possible carcinogenic effect in humans or experimental animals.

The scientific literature is surveyed for published data relevant to an assessment of carcinogenicity. Ad hoc Advisory Groups convened by IARC in 1984, 1989, 1991, 1993, 1998 and 2003 made recommendations as to which agents should be evaluated in the *Monographs* series. Recent recommendations are available on the *Monographs* programme web site (http://monographs.iarc.fr). IARC may schedule other agents for review as it becomes aware of new scientific information or as national health agencies identify an urgent public health need related to cancer.

As significant new data become available on an agent for which a *Monograph* exists, a re-evaluation may be made at a subsequent meeting, and a new *Monograph* published. In some cases it may be appropriate to review only the data published since a prior evaluation. This can be useful for updating a database, reviewing new data to resolve a previously open question or identifying new tumour sites associated with a carcinogenic agent. Major changes in an evaluation (e.g. a new classification in Group 1 or a determination that a mechanism does not operate in humans, see Part B, Section 6) are more appropriately addressed by a full review.

4. Data for the *Monographs*

Each *Monograph* reviews all pertinent epidemiological studies and cancer bioassays in experimental animals. Those judged inadequate

or irrelevant to the evaluation may be cited but not summarized. If a group of similar studies is not reviewed, the reasons are indicated.

Mechanistic and other relevant data are also reviewed. A *Monograph* does not necessarily cite all the mechanistic literature concerning the agent being evaluated (see Part B, Section 4). Only those data considered by the Working Group to be relevant to making the evaluation are included.

With regard to epidemiological studies, cancer bioassays, and mechanistic and other relevant data, only reports that have been published or accepted for publication in the openly available scientific literature are reviewed. The same publication requirement applies to studies originating from IARC, including meta-analyses or pooled analyses commissioned by IARC in advance of a meeting (see Part B, Section 2c). Data from government agency reports that are publicly available are also considered. Exceptionally, doctoral theses and other material that are in their final form and publicly available may be reviewed.

Exposure data and other information on an agent under consideration are also reviewed. In the sections on chemical and physical properties, on analysis, on production and use and on occurrence, published and unpublished sources of information may be considered.

Inclusion of a study does not imply acceptance of the adequacy of the study design or of the analysis and interpretation of the results, and limitations are clearly outlined in square brackets at the end of each study description (see Part B). The reasons for not giving further consideration to an individual study also are indicated in the square brackets.

5. Meeting participants

Five categories of participant can be present at *Monograph* meetings.

(a) The Working Group

The Working Group is responsible for the critical reviews and evaluations that are developed during the meeting. The tasks of Working Group Members are: (i) to ascertain that all appropriate data have been collected; (ii) to select the data relevant for the evaluation on the basis of scientific merit; (iii) to prepare accurate summaries of the data to enable the reader to follow the reasoning of the Working Group; (iv) to evaluate the results of epidemiological and experimental studies on cancer; (v) to evaluate data relevant to the understanding of mechanisms of carcinogenesis; and (vi) to make an overall evaluation of the carcinogenicity of the exposure to humans. Working Group Members generally have published significant research related to the carcinogenicity of the agents being reviewed, and IARC uses literature searches to identify most experts. Working Group Members are selected on the basis of (a) knowledge and experience and (b) absence of real or apparent conflicts of interests. Consideration is also given to demographic diversity and balance of scientific findings and views.

(b) Invited Specialists

Invited Specialists are experts who also have critical knowledge and experience but have a real or apparent conflict of interests. These experts are invited when necessary to assist in the Working Group by contributing their unique knowledge and experience during subgroup and plenary discussions. They may also contribute text on non-influential issues in the section on exposure, such as a general description of data on production and use (see Part B, Section 1). Invited Specialists do not serve as meeting chair or subgroup chair, draft text that pertains to the description or interpretation of cancer data, or participate in the evaluations.

(c) Representatives of national and international health agencies

Representatives of national and international health agencies often attend meetings because their agencies sponsor the programme or are interested in the subject of a meeting. Representatives do not serve as meeting chair or subgroup chair, draft any part of a *Monograph*, or participate in the evaluations.

(d) Observers with relevant scientific credentials

Observers with relevant scientific credentials may be admitted to a meeting by IARC in limited numbers. Attention will be given to achieving a balance of Observers from constituencies with differing perspectives. They are invited to observe the meeting and should not attempt to influence it. Observers do not serve as meeting chair or subgroup chair, draft any part of a *Monograph*, or participate in the evaluations. At the meeting, the meeting chair and subgroup chairs may grant Observers an opportunity to speak, generally after they have observed a discussion. Observers agree to respect the Guidelines for Observers at *IARC Monographs* meetings (available at http://monographs.iarc.fr).

(e) The IARC Secretariat

The IARC Secretariat consists of scientists who are designated by IARC and who have relevant expertise. They serve as rapporteurs and participate in all discussions. When requested by the meeting chair or subgroup chair, they may also draft text or prepare tables and analyses.

Before an invitation is extended, each potential participant, including the IARC Secretariat, completes the WHO Declaration of Interests to report financial interests, employment and consulting, and individual and institutional research support related to the subject of the meeting. IARC assesses these interests to determine whether there is a conflict that warrants some limitation on participation. The declarations are updated and reviewed again at the opening of the meeting. Interests related to the subject of the meeting are disclosed to the meeting participants and in the published volume (Cogliano *et al.*, 2004).

The names and principal affiliations of participants are available on the *Monographs* programme web site (http://monographs.iarc.fr) approximately two months before each meeting. It is not acceptable for Observers or third parties to contact other participants before a meeting or to lobby them at any time. Meeting participants are asked to report all such contacts to IARC (Cogliano *et al.*, 2005).

All participants are listed, with their principal affiliations, at the beginning of each volume. Each participant who is a Member of a Working Group serves as an individual scientist and not as a representative of any organization, government or industry.

6. Working procedures

A separate Working Group is responsible for developing each volume of *Monographs*. A volume contains one or more *Monographs*, which can cover either a single agent or several related agents. Approximately one year in advance of the meeting of a Working Group, the agents to be reviewed are announced on the *Monographs* programme web site (http://monographs.iarc.fr) and participants are selected by IARC staff in consultation with other experts. Subsequently, relevant biological and epidemiological data are collected by IARC from recognized sources of information on carcinogenesis, including data storage and retrieval systems such as PubMed. Meeting participants who are asked to prepare preliminary working papers for specific sections are expected to supplement the IARC literature searches with their own searches.

Industrial associations, labour unions and other knowledgeable organizations may be asked to provide input to the sections on production and use, although this involvement is not required as a general rule. Information on production and trade is obtained from governmental, trade and market research publications and, in some cases, by direct contact with industries. Separate production data on some agents may not be available for a variety of reasons (e.g. not collected or made public in all producing countries, production is small). Information on uses may be obtained from published sources but is often complemented by direct contact with manufacturers. Efforts are made to supplement this information with data from other national and international sources.

Six months before the meeting, the material obtained is sent to meeting participants to prepare preliminary working papers. The working papers are compiled by IARC staff and sent, before the meeting, to Working Group Members and Invited Specialists for review.

The Working Group meets at IARC for seven to eight days to discuss and finalize the texts and to formulate the evaluations. The objectives of the meeting are peer review and consensus. During the first few days, four subgroups (covering exposure data, cancer in humans, cancer in experimental animals, and mechanistic and other relevant data) review the working papers, develop a joint subgroup draft and write summaries. Care is taken to ensure that each study summary is written or reviewed by someone not associated with the study being considered. During the last few days, the Working Group meets in plenary session to review the subgroup drafts and develop the evaluations. As a result, the entire volume is the joint product of the Working Group, and there are no individually authored sections.

IARC Working Groups strive to achieve a consensus evaluation. Consensus reflects broad agreement among Working Group Members, but not necessarily unanimity. The chair may elect to poll Working Group Members to determine the diversity of scientific opinion on issues where consensus is not readily apparent.

After the meeting, the master copy is verified by consulting the original literature, edited and prepared for publication. The aim is to publish the volume within six months of the Working Group meeting. A summary of the outcome is available on the *Monographs* programme web site soon after the meeting.

B. SCIENTIFIC REVIEW AND EVALUATION

The available studies are summarized by the Working Group, with particular regard to the qualitative aspects discussed below. In general, numerical findings are indicated as they appear in the original report; units are converted when necessary for easier comparison. The Working Group may conduct additional analyses of the published data and use them in their assessment of the evidence; the results of such supplementary analyses are given in square brackets. When an important aspect of a study that directly impinges on its interpretation should be brought to the attention of the reader, a Working Group comment is given in square brackets.

The scope of the *IARC Monographs* programme has expanded beyond chemicals to include complex mixtures, occupational exposures, physical and biological agents, lifestyle factors and other potentially carcinogenic exposures. Over time, the structure of a *Monograph* has evolved to include the following sections:

Exposure data
Studies of cancer in humans
Studies of cancer in experimental animals
Mechanistic and other relevant data
Summary
Evaluation and rationale

In addition, a section of General Remarks at the front of the volume discusses the reasons the agents were scheduled for evaluation and some key issues the Working Group encountered during the meeting.

This part of the Preamble discusses the types of evidence considered and summarized in each section of a *Monograph*, followed by the scientific criteria that guide the evaluations.

1. Exposure data

Each *Monograph* includes general information on the agent: this information may vary substantially between agents and must be adapted accordingly. Also included is information on production and use (when appropriate), methods of analysis and detection, occurrence, and sources and routes of human occupational and environmental exposures. Depending on the agent, regulations and guidelines for use may be presented.

(a) General information on the agent

For chemical agents, sections on chemical and physical data are included: the Chemical Abstracts Service Registry Number, the latest primary name and the IUPAC systematic name are recorded; other synonyms are given, but the list is not necessarily comprehensive. Information on chemical and physical properties that are relevant to identification, occurrence and biological activity is included. A description of technical products of chemicals includes trade names, relevant specifications and available information on composition and impurities. Some of the trade names given may be those of mixtures in which the agent being evaluated is only one of the ingredients.

For biological agents, taxonomy, structure and biology are described, and the degree of variability is indicated. Mode of replication, life cycle, target cells, persistence, latency, host response and clinical disease other than cancer are also presented.

For physical agents that are forms of radiation, energy and range of the radiation are included. For foreign bodies, fibres and respirable particles, size range and relative dimensions are indicated.

For agents such as mixtures, drugs or lifestyle factors, a description of the agent, including its composition, is given.

Whenever appropriate, other information, such as historical perspectives or the description of an industry or habit, may be included.

(b) Analysis and detection

An overview of methods of analysis and detection of the agent is presented, including their sensitivity, specificity and reproducibility. Methods widely used for regulatory purposes are emphasized. Methods for monitoring human exposure are also given. No critical evaluation or recommendation of any method is meant or implied.

(c) Production and use

The dates of first synthesis and of first commercial production of a chemical, mixture or other agent are provided when available; for agents that do not occur naturally, this information may allow a reasonable estimate to be made of the date before which no human exposure to the agent could have occurred. The dates of first reported occurrence of an exposure are also provided when available. In addition, methods of synthesis used in past and present commercial production and different methods of production, which may give rise to different impurities, are described.

The countries where companies report production of the agent, and the number of companies in each country, are identified. Available data on production, international trade and uses are

obtained for representative regions. It should not, however, be inferred that those areas or nations are necessarily the sole or major sources or users of the agent. Some identified uses may not be current or major applications, and the coverage is not necessarily comprehensive. In the case of drugs, mention of their therapeutic uses does not necessarily represent current practice nor does it imply judgement as to their therapeutic efficacy.

(d) Occurrence and exposure

Information on the occurrence of an agent in the environment is obtained from data derived from the monitoring and surveillance of levels in occupational environments, air, water, soil, plants, foods and animal and human tissues. When available, data on the generation, persistence and bioaccumulation of the agent are also included. Such data may be available from national databases.

Data that indicate the extent of past and present human exposure, the sources of exposure, the people most likely to be exposed and the factors that contribute to the exposure are reported. Information is presented on the range of human exposure, including occupational and environmental exposures. This includes relevant findings from both developed and developing countries. Some of these data are not distributed widely and may be available from government reports and other sources. In the case of mixtures, industries, occupations or processes, information is given about all agents known to be present. For processes, industries and occupations, a historical description is also given, noting variations in chemical composition, physical properties and levels of occupational exposure with date and place. For biological agents, the epidemiology of infection is described.

(e) Regulations and guidelines

Statements concerning regulations and guidelines (e.g. occupational exposure limits, maximal levels permitted in foods and water, pesticide registrations) are included, but they may not reflect the most recent situation, since such limits are continuously reviewed and modified. The absence of information on regulatory status for a country should not be taken to imply that that country does not have regulations with regard to the exposure. For biological agents, legislation and control, including vaccination and therapy, are described.

2. Studies of cancer in humans

This section includes all pertinent epidemiological studies (see Part A, Section 4). Studies of biomarkers are included when they are relevant to an evaluation of carcinogenicity to humans.

(a) Types of study considered

Several types of epidemiological study contribute to the assessment of carcinogenicity in humans — cohort studies, case–control studies, correlation (or ecological) studies and intervention studies. Rarely, results from randomized trials may be available. Case reports and case series of cancer in humans may also be reviewed.

Cohort and case–control studies relate individual exposures under study to the occurrence of cancer in individuals and provide an estimate of effect (such as relative risk) as the main measure of association. Intervention studies may provide strong evidence for making causal inferences, as exemplified by cessation of smoking and the subsequent decrease in risk for lung cancer.

In correlation studies, the units of investigation are usually whole populations (e.g. in particular geographical areas or at particular times), and cancer frequency is related to a summary measure of the exposure of the population

to the agent under study. In correlation studies, individual exposure is not documented, which renders this kind of study more prone to confounding. In some circumstances, however, correlation studies may be more informative than analytical study designs (see, for example, the *Monograph* on arsenic in drinking-water; IARC, 2004).

In some instances, case reports and case series have provided important information about the carcinogenicity of an agent. These types of study generally arise from a suspicion, based on clinical experience, that the concurrence of two events — that is, a particular exposure and occurrence of a cancer — has happened rather more frequently than would be expected by chance. Case reports and case series usually lack complete ascertainment of cases in any population, definition or enumeration of the population at risk and estimation of the expected number of cases in the absence of exposure.

The uncertainties that surround the interpretation of case reports, case series and correlation studies make them inadequate, except in rare instances, to form the sole basis for inferring a causal relationship. When taken together with case–control and cohort studies, however, these types of study may add materially to the judgement that a causal relationship exists.

Epidemiological studies of benign neoplasms, presumed preneoplastic lesions and other end-points thought to be relevant to cancer are also reviewed. They may, in some instances, strengthen inferences drawn from studies of cancer itself.

(b) Quality of studies considered

It is necessary to take into account the possible roles of bias, confounding and chance in the interpretation of epidemiological studies. Bias is the effect of factors in study design or execution that lead erroneously to a stronger or weaker association than in fact exists between an agent and disease. Confounding is a form of bias that occurs when the relationship with disease is made to appear stronger or weaker than it truly is as a result of an association between the apparent causal factor and another factor that is associated with either an increase or decrease in the incidence of the disease. The role of chance is related to biological variability and the influence of sample size on the precision of estimates of effect.

In evaluating the extent to which these factors have been minimized in an individual study, consideration is given to several aspects of design and analysis as described in the report of the study. For example, when suspicion of carcinogenicity arises largely from a single small study, careful consideration is given when interpreting subsequent studies that included these data in an enlarged population. Most of these considerations apply equally to case–control, cohort and correlation studies. Lack of clarity of any of these aspects in the reporting of a study can decrease its credibility and the weight given to it in the final evaluation of the exposure.

First, the study population, disease (or diseases) and exposure should have been well defined by the authors. Cases of disease in the study population should have been identified in a way that was independent of the exposure of interest, and exposure should have been assessed in a way that was not related to disease status.

Second, the authors should have taken into account — in the study design and analysis — other variables that can influence the risk of disease and may have been related to the exposure of interest. Potential confounding by such variables should have been dealt with either in the design of the study, such as by matching, or in the analysis, by statistical adjustment. In cohort studies, comparisons with local rates of disease may or may not be more appropriate than those with national rates. Internal comparisons of frequency of disease among individuals at different levels of exposure are also desirable in cohort studies, since they minimize the potential for

confounding related to the difference in risk factors between an external reference group and the study population.

Third, the authors should have reported the basic data on which the conclusions are founded, even if sophisticated statistical analyses were employed. At the very least, they should have given the numbers of exposed and unexposed cases and controls in a case–control study and the numbers of cases observed and expected in a cohort study. Further tabulations by time since exposure began and other temporal factors are also important. In a cohort study, data on all cancer sites and all causes of death should have been given, to reveal the possibility of reporting bias. In a case–control study, the effects of investigated factors other than the exposure of interest should have been reported.

Finally, the statistical methods used to obtain estimates of relative risk, absolute rates of cancer, confidence intervals and significance tests, and to adjust for confounding should have been clearly stated by the authors. These methods have been reviewed for case–control studies (Breslow & Day, 1980) and for cohort studies (Breslow & Day, 1987).

(c) Meta-analyses and pooled analyses

Independent epidemiological studies of the same agent may lead to results that are difficult to interpret. Combined analyses of data from multiple studies are a means of resolving this ambiguity, and well conducted analyses can be considered. There are two types of combined analysis. The first involves combining summary statistics such as relative risks from individual studies (meta-analysis) and the second involves a pooled analysis of the raw data from the individual studies (pooled analysis) (Greenland, 1998).

The advantages of combined analyses are increased precision due to increased sample size and the opportunity to explore potential confounders, interactions and modifying effects that may explain heterogeneity among studies in more detail. A disadvantage of combined analyses is the possible lack of compatibility of data from various studies due to differences in subject recruitment, procedures of data collection, methods of measurement and effects of unmeasured co-variates that may differ among studies. Despite these limitations, well conducted combined analyses may provide a firmer basis than individual studies for drawing conclusions about the potential carcinogenicity of agents.

IARC may commission a meta-analysis or pooled analysis that is pertinent to a particular *Monograph* (see Part A, Section 4). Additionally, as a means of gaining insight from the results of multiple individual studies, ad hoc calculations that combine data from different studies may be conducted by the Working Group during the course of a *Monograph* meeting. The results of such original calculations, which would be specified in the text by presentation in square brackets, might involve updates of previously conducted analyses that incorporate the results of more recent studies or de-novo analyses. Irrespective of the source of data for the meta-analyses and pooled analyses, it is important that the same criteria for data quality be applied as those that would be applied to individual studies and to ensure also that sources of heterogeneity between studies be taken into account.

(d) Temporal effects

Detailed analyses of both relative and absolute risks in relation to temporal variables, such as age at first exposure, time since first exposure, duration of exposure, cumulative exposure, peak exposure (when appropriate) and time since cessation of exposure, are reviewed and summarized when available. Analyses of temporal relationships may be useful in making causal inferences. In addition, such analyses may suggest whether a carcinogen acts early or late in the process of carcinogenesis, although, at best, they

allow only indirect inferences about mechanisms of carcinogenesis.

(e) Use of biomarkers in epidemiological studies

Biomarkers indicate molecular, cellular or other biological changes and are increasingly used in epidemiological studies for various purposes (IARC, 1991; Vainio *et al.*, 1992; Toniolo *et al.*, 1997; Vineis *et al.*, 1999; Buffler *et al.*, 2004). These may include evidence of exposure, of early effects, of cellular, tissue or organism responses, of individual susceptibility or host responses, and inference of a mechanism (see Part B, Section 4b). This is a rapidly evolving field that encompasses developments in genomics, epigenomics and other emerging technologies.

Molecular epidemiological data that identify associations between genetic polymorphisms and interindividual differences in susceptibility to the agent(s) being evaluated may contribute to the identification of carcinogenic hazards to humans. If the polymorphism has been demonstrated experimentally to modify the functional activity of the gene product in a manner that is consistent with increased susceptibility, these data may be useful in making causal inferences. Similarly, molecular epidemiological studies that measure cell functions, enzymes or metabolites that are thought to be the basis of susceptibility may provide evidence that reinforces biological plausibility. It should be noted, however, that when data on genetic susceptibility originate from multiple comparisons that arise from subgroup analyses, this can generate false-positive results and inconsistencies across studies, and such data therefore require careful evaluation. If the known phenotype of a genetic polymorphism can explain the carcinogenic mechanism of the agent being evaluated, data on this phenotype may be useful in making causal inferences.

(f) Criteria for causality

After the quality of individual epidemiological studies of cancer has been summarized and assessed, a judgement is made concerning the strength of evidence that the agent in question is carcinogenic to humans. In making its judgement, the Working Group considers several criteria for causality (Hill, 1965). A strong association (e.g. a large relative risk) is more likely to indicate causality than a weak association, although it is recognized that estimates of effect of small magnitude do not imply lack of causality and may be important if the disease or exposure is common. Associations that are replicated in several studies of the same design or that use different epidemiological approaches or under different circumstances of exposure are more likely to represent a causal relationship than isolated observations from single studies. If there are inconsistent results among investigations, possible reasons are sought (such as differences in exposure), and results of studies that are judged to be of high quality are given more weight than those of studies that are judged to be methodologically less sound.

If the risk increases with the exposure, this is considered to be a strong indication of causality, although the absence of a graded response is not necessarily evidence against a causal relationship. The demonstration of a decline in risk after cessation of or reduction in exposure in individuals or in whole populations also supports a causal interpretation of the findings.

Several scenarios may increase confidence in a causal relationship. On the one hand, an agent may be specific in causing tumours at one site or of one morphological type. On the other, carcinogenicity may be evident through the causation of multiple tumour types. Temporality, precision of estimates of effect, biological plausibility and coherence of the overall database are considered. Data on biomarkers may be employed in

an assessment of the biological plausibility of epidemiological observations.

Although rarely available, results from randomized trials that show different rates of cancer among exposed and unexposed individuals provide particularly strong evidence for causality.

When several epidemiological studies show little or no indication of an association between an exposure and cancer, a judgement may be made that, in the aggregate, they show evidence of lack of carcinogenicity. Such a judgement requires first that the studies meet, to a sufficient degree, the standards of design and analysis described above. Specifically, the possibility that bias, confounding or misclassification of exposure or outcome could explain the observed results should be considered and excluded with reasonable certainty. In addition, all studies that are judged to be methodologically sound should (a) be consistent with an estimate of effect of unity for any observed level of exposure, (b) when considered together, provide a pooled estimate of relative risk that is at or near to unity, and (c) have a narrow confidence interval, due to sufficient population size. Moreover, no individual study nor the pooled results of all the studies should show any consistent tendency that the relative risk of cancer increases with increasing level of exposure. It is important to note that evidence of lack of carcinogenicity obtained from several epidemiological studies can apply only to the type(s) of cancer studied, to the dose levels reported, and to the intervals between first exposure and disease onset observed in these studies. Experience with human cancer indicates that the period from first exposure to the development of clinical cancer is sometimes longer than 20 years; latent periods substantially shorter than 30 years cannot provide evidence for lack of carcinogenicity.

3. Studies of cancer in experimental animals

All known human carcinogens that have been studied adequately for carcinogenicity in experimental animals have produced positive results in one or more animal species (Wilbourn *et al.*, 1986; Tomatis *et al.*, 1989). For several agents (e.g. aflatoxins, diethylstilbestrol, solar radiation, vinyl chloride), carcinogenicity in experimental animals was established or highly suspected before epidemiological studies confirmed their carcinogenicity in humans (Vainio *et al.*, 1995). Although this association cannot establish that all agents that cause cancer in experimental animals also cause cancer in humans, it is biologically plausible that agents for which there is *sufficient evidence of carcinogenicity* in experimental animals (see Part B, Section 6b) also present a carcinogenic hazard to humans. Accordingly, in the absence of additional scientific information, these agents are considered to pose a carcinogenic hazard to humans. Examples of additional scientific information are data that demonstrate that a given agent causes cancer in animals through a species-specific mechanism that does not operate in humans or data that demonstrate that the mechanism in experimental animals also operates in humans (see Part B, Section 6).

Consideration is given to all available long-term studies of cancer in experimental animals with the agent under review (see Part A, Section 4). In all experimental settings, the nature and extent of impurities or contaminants present in the agent being evaluated are given when available. Animal species, strain (including genetic background where applicable), sex, numbers per group, age at start of treatment, route of exposure, dose levels, duration of exposure, survival and information on tumours (incidence, latency, severity or multiplicity of neoplasms or preneoplastic lesions) are reported. Those studies in experimental animals that are judged to be irrelevant to the evaluation or judged to be inadequate

(e.g. too short a duration, too few animals, poor survival; see below) may be omitted. Guidelines for conducting long-term carcinogenicity experiments have been published (e.g. OECD, 2002).

Other studies considered may include: experiments in which the agent was administered in the presence of factors that modify carcinogenic effects (e.g. initiation–promotion studies, co-carcinogenicity studies and studies in genetically modified animals); studies in which the end-point was not cancer but a defined precancerous lesion; experiments on the carcinogenicity of known metabolites and derivatives; and studies of cancer in non-laboratory animals (e.g. livestock and companion animals) exposed to the agent.

For studies of mixtures, consideration is given to the possibility that changes in the physicochemical properties of the individual substances may occur during collection, storage, extraction, concentration and delivery. Another consideration is that chemical and toxicological interactions of components in a mixture may alter dose–response relationships. The relevance to human exposure of the test mixture administered in the animal experiment is also assessed. This may involve consideration of the following aspects of the mixture tested: (i) physical and chemical characteristics, (ii) identified constituents that may indicate the presence of a class of substances and (iii) the results of genetic toxicity and related tests.

The relevance of results obtained with an agent that is analogous (e.g. similar in structure or of a similar virus genus) to that being evaluated is also considered. Such results may provide biological and mechanistic information that is relevant to the understanding of the process of carcinogenesis in humans and may strengthen the biological plausibility that the agent being evaluated is carcinogenic to humans (see Part B, Section 2f).

(a) Qualitative aspects

An assessment of carcinogenicity involves several considerations of qualitative importance, including (i) the experimental conditions under which the test was performed, including route, schedule and duration of exposure, species, strain (including genetic background where applicable), sex, age and duration of follow-up; (ii) the consistency of the results, for example, across species and target organ(s); (iii) the spectrum of neoplastic response, from preneoplastic lesions and benign tumours to malignant neoplasms; and (iv) the possible role of modifying factors.

Considerations of importance in the interpretation and evaluation of a particular study include: (i) how clearly the agent was defined and, in the case of mixtures, how adequately the sample characterization was reported; (ii) whether the dose was monitored adequately, particularly in inhalation experiments; (iii) whether the doses, duration of treatment and route of exposure were appropriate; (iv) whether the survival of treated animals was similar to that of controls; (v) whether there were adequate numbers of animals per group; (vi) whether both male and female animals were used; (vii) whether animals were allocated randomly to groups; (viii) whether the duration of observation was adequate; and (ix) whether the data were reported and analysed adequately.

When benign tumours (a) occur together with and originate from the same cell type as malignant tumours in an organ or tissue in a particular study and (b) appear to represent a stage in the progression to malignancy, they are usually combined in the assessment of tumour incidence (Huff *et al.*, 1989). The occurrence of lesions presumed to be preneoplastic may in certain instances aid in assessing the biological plausibility of any neoplastic response observed. If an agent induces only benign neoplasms that appear to be end-points that do not readily undergo

transition to malignancy, the agent should nevertheless be suspected of being carcinogenic and requires further investigation.

(b) Quantitative aspects

The probability that tumours will occur may depend on the species, sex, strain, genetic background and age of the animal, and on the dose, route, timing and duration of the exposure. Evidence of an increased incidence of neoplasms with increasing levels of exposure strengthens the inference of a causal association between the exposure and the development of neoplasms.

The form of the dose–response relationship can vary widely, depending on the particular agent under study and the target organ. Mechanisms such as induction of DNA damage or inhibition of repair, altered cell division and cell death rates and changes in intercellular communication are important determinants of dose–response relationships for some carcinogens. Since many chemicals require metabolic activation before being converted to their reactive intermediates, both metabolic and toxicokinetic aspects are important in determining the dose–response pattern. Saturation of steps such as absorption, activation, inactivation and elimination may produce nonlinearity in the dose–response relationship (Hoel et al., 1983; Gart *et al.*, 1986), as could saturation of processes such as DNA repair. The dose–response relationship can also be affected by differences in survival among the treatment groups.

(c) Statistical analyses

Factors considered include the adequacy of the information given for each treatment group: (i) number of animals studied and number examined histologically, (ii) number of animals with a given tumour type and (iii) length of survival. The statistical methods used should be clearly stated and should be the generally accepted techniques refined for this purpose (Peto *et al.*, 1980; Gart *et al.*, 1986; Portier & Bailer, 1989; Bieler & Williams, 1993). The choice of the most appropriate statistical method requires consideration of whether or not there are differences in survival among the treatment groups; for example, reduced survival because of non-tumour-related mortality can preclude the occurrence of tumours later in life. When detailed information on survival is not available, comparisons of the proportions of tumour-bearing animals among the effective number of animals (alive at the time the first tumour was discovered) can be useful when significant differences in survival occur before tumours appear. The lethality of the tumour also requires consideration: for rapidly fatal tumours, the time of death provides an indication of the time of tumour onset and can be assessed using life-table methods; non-fatal or incidental tumours that do not affect survival can be assessed using methods such as the Mantel-Haenzel test for changes in tumour prevalence. Because tumour lethality is often difficult to determine, methods such as the Poly-K test that do not require such information can also be used. When results are available on the number and size of tumours seen in experimental animals (e.g. papillomas on mouse skin, liver tumours observed through nuclear magnetic resonance tomography), other more complicated statistical procedures may be needed (Sherman *et al.*, 1994; Dunson *et al.*, 2003).

Formal statistical methods have been developed to incorporate historical control data into the analysis of data from a given experiment. These methods assign an appropriate weight to historical and concurrent controls on the basis of the extent of between-study and within-study variability: less weight is given to historical controls when they show a high degree of variability, and greater weight when they show little variability. It is generally not appropriate to discount a tumour response that is significantly increased compared with concurrent controls by arguing that it falls within the range of historical controls,

particularly when historical controls show high between-study variability and are, thus, of little relevance to the current experiment. In analysing results for uncommon tumours, however, the analysis may be improved by considering historical control data, particularly when between-study variability is low. Historical controls should be selected to resemble the concurrent controls as closely as possible with respect to species, gender and strain, as well as other factors such as basal diet and general laboratory environment, which may affect tumour-response rates in control animals (Haseman *et al.*, 1984; Fung *et al.*, 1996; Greim *et al.*, 2003).

Although meta-analyses and combined analyses are conducted less frequently for animal experiments than for epidemiological studies due to differences in animal strains, they can be useful aids in interpreting animal data when the experimental protocols are sufficiently similar.

4. Mechanistic and other relevant data

Mechanistic and other relevant data may provide evidence of carcinogenicity and also help in assessing the relevance and importance of findings of cancer in animals and in humans. The nature of the mechanistic and other relevant data depends on the biological activity of the agent being considered. The Working Group considers representative studies to give a concise description of the relevant data and issues that they consider to be important; thus, not every available study is cited. Relevant topics may include toxicokinetics, mechanisms of carcinogenesis, susceptible individuals, populations and life-stages, other relevant data and other adverse effects. When data on biomarkers are informative about the mechanisms of carcinogenesis, they are included in this section.

These topics are not mutually exclusive; thus, the same studies may be discussed in more than one subsection. For example, a mutation in a gene that codes for an enzyme that metabolizes the agent under study could be discussed in the subsections on toxicokinetics, mechanisms and individual susceptibility if it also exists as an inherited polymorphism.

(a) Toxicokinetic data

Toxicokinetics refers to the absorption, distribution, metabolism and elimination of agents in humans, experimental animals and, where relevant, cellular systems. Examples of kinetic factors that may affect dose–response relationships include uptake, deposition, biopersistence and half-life in tissues, protein binding, metabolic activation and detoxification. Studies that indicate the metabolic fate of the agent in humans and in experimental animals are summarized briefly, and comparisons of data from humans and animals are made when possible. Comparative information on the relationship between exposure and the dose that reaches the target site may be important for the extrapolation of hazards between species and in clarifying the role of in-vitro findings.

(b) Data on mechanisms of carcinogenesis

To provide focus, the Working Group attempts to identify the possible mechanisms by which the agent may increase the risk of cancer. For each possible mechanism, a representative selection of key data from humans and experimental systems is summarized. Attention is given to gaps in the data and to data that suggests that more than one mechanism may be operating. The relevance of the mechanism to humans is discussed, in particular, when mechanistic data are derived from experimental model systems. Changes in the affected organs, tissues or cells can be divided into three non-exclusive levels as described below.

(i) Changes in physiology

Physiological changes refer to exposure-related modifications to the physiology and/or response of cells, tissues and organs. Examples of potentially adverse physiological changes include mitogenesis, compensatory cell division, escape from apoptosis and/or senescence, presence of inflammation, hyperplasia, metaplasia and/or preneoplasia, angiogenesis, alterations in cellular adhesion, changes in steroidal hormones and changes in immune surveillance.

(ii) Functional changes at the cellular level

Functional changes refer to exposure-related alterations in the signalling pathways used by cells to manage critical processes that are related to increased risk for cancer. Examples of functional changes include modified activities of enzymes involved in the metabolism of xenobiotics, alterations in the expression of key genes that regulate DNA repair, alterations in cyclin-dependent kinases that govern cell cycle progression, changes in the patterns of post-translational modifications of proteins, changes in regulatory factors that alter apoptotic rates, changes in the secretion of factors related to the stimulation of DNA replication and transcription and changes in gap–junction-mediated intercellular communication.

(iii) Changes at the molecular level

Molecular changes refer to exposure-related changes in key cellular structures at the molecular level, including, in particular, genotoxicity. Examples of molecular changes include formation of DNA adducts and DNA strand breaks, mutations in genes, chromosomal aberrations, aneuploidy and changes in DNA methylation patterns. Greater emphasis is given to irreversible effects.

The use of mechanistic data in the identification of a carcinogenic hazard is specific to the mechanism being addressed and is not readily described for every possible level and mechanism discussed above.

Genotoxicity data are discussed here to illustrate the key issues involved in the evaluation of mechanistic data.

Tests for genetic and related effects are described in view of the relevance of gene mutation and chromosomal aberration/aneuploidy to carcinogenesis (Vainio *et al.*, 1992; McGregor *et al.*, 1999). The adequacy of the reporting of sample characterization is considered and, when necessary, commented upon; with regard to complex mixtures, such comments are similar to those described for animal carcinogenicity tests. The available data are interpreted critically according to the end-points detected, which may include DNA damage, gene mutation, sister chromatid exchange, micronucleus formation, chromosomal aberrations and aneuploidy. The concentrations employed are given, and mention is made of whether the use of an exogenous metabolic system in vitro affected the test result. These data are listed in tabular form by phylogenetic classification.

Positive results in tests using prokaryotes, lower eukaryotes, insects, plants and cultured mammalian cells suggest that genetic and related effects could occur in mammals. Results from such tests may also give information on the types of genetic effect produced and on the involvement of metabolic activation. Some end-points described are clearly genetic in nature (e.g. gene mutations), while others are associated with genetic effects (e.g. unscheduled DNA synthesis). In-vitro tests for tumour promotion, cell transformation and gap–junction intercellular communication may be sensitive to changes that are not necessarily the result of genetic alterations but that may have specific relevance to the process of carcinogenesis. Critical appraisals of these tests have been published (Montesano *et al.*, 1986; McGregor *et al.*, 1999).

Genetic or other activity manifest in humans and experimental mammals is regarded to be of

greater relevance than that in other organisms. The demonstration that an agent can induce gene and chromosomal mutations in mammals in vivo indicates that it may have carcinogenic activity. Negative results in tests for mutagenicity in selected tissues from animals treated in vivo provide less weight, partly because they do not exclude the possibility of an effect in tissues other than those examined. Moreover, negative results in short-term tests with genetic end-points cannot be considered to provide evidence that rules out the carcinogenicity of agents that act through other mechanisms (e.g. receptor-mediated effects, cellular toxicity with regenerative cell division, peroxisome proliferation) (Vainio *et al.*, 1992). Factors that may give misleading results in short-term tests have been discussed in detail elsewhere (Montesano *et al.*, 1986; McGregor *et al.*, 1999).

When there is evidence that an agent acts by a specific mechanism that does not involve genotoxicity (e.g. hormonal dysregulation, immune suppression, and formation of calculi and other deposits that cause chronic irritation), that evidence is presented and reviewed critically in the context of rigorous criteria for the operation of that mechanism in carcinogenesis (e.g. Capen *et al.*, 1999).

For biological agents such as viruses, bacteria and parasites, other data relevant to carcinogenicity may include descriptions of the pathology of infection, integration and expression of viruses, and genetic alterations seen in human tumours. Other observations that might comprise cellular and tissue responses to infection, immune response and the presence of tumour markers are also considered.

For physical agents that are forms of radiation, other data relevant to carcinogenicity may include descriptions of damaging effects at the physiological, cellular and molecular level, as for chemical agents, and descriptions of how these effects occur. 'Physical agents' may also be considered to comprise foreign bodies, such as surgical implants of various kinds, and poorly soluble fibres, dusts and particles of various sizes, the pathogenic effects of which are a result of their physical presence in tissues or body cavities. Other relevant data for such materials may include characterization of cellular, tissue and physiological reactions to these materials and descriptions of pathological conditions other than neoplasia with which they may be associated.

(c) Other data relevant to mechanisms

A description is provided of any structure–activity relationships that may be relevant to an evaluation of the carcinogenicity of an agent, the toxicological implications of the physical and chemical properties, and any other data relevant to the evaluation that are not included elsewhere.

High-output data, such as those derived from gene expression microarrays, and high-throughput data, such as those that result from testing hundreds of agents for a single end-point, pose a unique problem for the use of mechanistic data in the evaluation of a carcinogenic hazard. In the case of high-output data, there is the possibility to overinterpret changes in individual end-points (e.g. changes in expression in one gene) without considering the consistency of that finding in the broader context of the other end-points (e.g. other genes with linked transcriptional control). High-output data can be used in assessing mechanisms, but all end-points measured in a single experiment need to be considered in the proper context. For high-throughput data, where the number of observations far exceeds the number of end-points measured, their utility for identifying common mechanisms across multiple agents is enhanced. These data can be used to identify mechanisms that not only seem plausible, but also have a consistent pattern of carcinogenic response across entire classes of related compounds.

(d) Susceptibility data

Individuals, populations and life-stages may have greater or lesser susceptibility to an agent, based on toxicokinetics, mechanisms of carcinogenesis and other factors. Examples of host and genetic factors that affect individual susceptibility include sex, genetic polymorphisms of genes involved in the metabolism of the agent under evaluation, differences in metabolic capacity due to life-stage or the presence of disease, differences in DNA repair capacity, competition for or alteration of metabolic capacity by medications or other chemical exposures, pre-existing hormonal imbalance that is exacerbated by a chemical exposure, a suppressed immune system, periods of higher-than-usual tissue growth or regeneration and genetic polymorphisms that lead to differences in behaviour (e.g. addiction). Such data can substantially increase the strength of the evidence from epidemiological data and enhance the linkage of in-vivo and in-vitro laboratory studies to humans.

(e) Data on other adverse effects

Data on acute, subchronic and chronic adverse effects relevant to the cancer evaluation are summarized. Adverse effects that confirm distribution and biological effects at the sites of tumour development, or alterations in physiology that could lead to tumour development, are emphasized. Effects on reproduction, embryonic and fetal survival and development are summarized briefly. The adequacy of epidemiological studies of reproductive outcome and genetic and related effects in humans is judged by the same criteria as those applied to epidemiological studies of cancer, but fewer details are given.

5. Summary

This section is a summary of data presented in the preceding sections. Summaries can be found on the *Monographs* programme web site (http://monographs.iarc.fr).

(a) Exposure data

Data are summarized, as appropriate, on the basis of elements such as production, use, occurrence and exposure levels in the workplace and environment and measurements in human tissues and body fluids. Quantitative data and time trends are given to compare exposures in different occupations and environmental settings. Exposure to biological agents is described in terms of transmission, prevalence and persistence of infection.

(b) Cancer in humans

Results of epidemiological studies pertinent to an assessment of human carcinogenicity are summarized. When relevant, case reports and correlation studies are also summarized. The target organ(s) or tissue(s) in which an increase in cancer was observed is identified. Dose–response and other quantitative data may be summarized when available.

(c) Cancer in experimental animals

Data relevant to an evaluation of carcinogenicity in animals are summarized. For each animal species, study design and route of administration, it is stated whether an increased incidence, reduced latency, or increased severity or multiplicity of neoplasms or preneoplastic lesions were observed, and the tumour sites are indicated. If the agent produced tumours after prenatal exposure or in single-dose experiments, this is also mentioned. Negative findings, inverse relationships, dose–response and other quantitative data are also summarized.

(d) Mechanistic and other relevant data

Data relevant to the toxicokinetics (absorption, distribution, metabolism, elimination) and

the possible mechanism(s) of carcinogenesis (e.g. genetic toxicity, epigenetic effects) are summarized. In addition, information on susceptible individuals, populations and life-stages is summarized. This section also reports on other toxic effects, including reproductive and developmental effects, as well as additional relevant data that are considered to be important.

6. Evaluation and rationale

Evaluations of the strength of the evidence for carcinogenicity arising from human and experimental animal data are made, using standard terms. The strength of the mechanistic evidence is also characterized.

It is recognized that the criteria for these evaluations, described below, cannot encompass all of the factors that may be relevant to an evaluation of carcinogenicity. In considering all of the relevant scientific data, the Working Group may assign the agent to a higher or lower category than a strict interpretation of these criteria would indicate.

These categories refer only to the strength of the evidence that an exposure is carcinogenic and not to the extent of its carcinogenic activity (potency). A classification may change as new information becomes available.

An evaluation of the degree of evidence is limited to the materials tested, as defined physically, chemically or biologically. When the agents evaluated are considered by the Working Group to be sufficiently closely related, they may be grouped together for the purpose of a single evaluation of the degree of evidence.

(a) Carcinogenicity in humans

The evidence relevant to carcinogenicity from studies in humans is classified into one of the following categories:

***Sufficient evidence of carcinogenicity*:** The Working Group considers that a causal relationship has been established between exposure to the agent and human cancer. That is, a positive relationship has been observed between the exposure and cancer in studies in which chance, bias and confounding could be ruled out with reasonable confidence. A statement that there is *sufficient evidence* is followed by a separate sentence that identifies the target organ(s) or tissue(s) where an increased risk of cancer was observed in humans. Identification of a specific target organ or tissue does not preclude the possibility that the agent may cause cancer at other sites.

***Limited evidence of carcinogenicity*:** A positive association has been observed between exposure to the agent and cancer for which a causal interpretation is considered by the Working Group to be credible, but chance, bias or confounding could not be ruled out with reasonable confidence.

***Inadequate evidence of carcinogenicity*:** The available studies are of insufficient quality, consistency or statistical power to permit a conclusion regarding the presence or absence of a causal association between exposure and cancer, or no data on cancer in humans are available.

***Evidence suggesting lack of carcinogenicity*:** There are several adequate studies covering the full range of levels of exposure that humans are known to encounter, which are mutually consistent in not showing a positive association between exposure to the agent and any studied cancer at any observed level of exposure. The results from these studies alone or combined should have narrow confidence intervals with an upper limit close to the null value (e.g. a relative risk of 1.0). Bias and confounding should be ruled out with reasonable confidence, and the studies should have an adequate length of follow-up. A conclusion of *evidence suggesting lack of carcinogenicity* is inevitably limited to the cancer sites, conditions and levels of exposure, and length of observation covered by the available studies. In

addition, the possibility of a very small risk at the levels of exposure studied can never be excluded.

In some instances, the above categories may be used to classify the degree of evidence related to carcinogenicity in specific organs or tissues.

When the available epidemiological studies pertain to a mixture, process, occupation or industry, the Working Group seeks to identify the specific agent considered most likely to be responsible for any excess risk. The evaluation is focused as narrowly as the available data on exposure and other aspects permit.

(b) Carcinogenicity in experimental animals

Carcinogenicity in experimental animals can be evaluated using conventional bioassays, bioassays that employ genetically modified animals, and other in-vivo bioassays that focus on one or more of the critical stages of carcinogenesis. In the absence of data from conventional long-term bioassays or from assays with neoplasia as the end-point, consistently positive results in several models that address several stages in the multistage process of carcinogenesis should be considered in evaluating the degree of evidence of carcinogenicity in experimental animals.

The evidence relevant to carcinogenicity in experimental animals is classified into one of the following categories:

***Sufficient evidence of carcinogenicity*:** The Working Group considers that a causal relationship has been established between the agent and an increased incidence of malignant neoplasms or of an appropriate combination of benign and malignant neoplasms in (a) two or more species of animals or (b) two or more independent studies in one species carried out at different times or in different laboratories or under different protocols. An increased incidence of tumours in both sexes of a single species in a well conducted study, ideally conducted under Good Laboratory Practices, can also provide *sufficient evidence*.

A single study in one species and sex might be considered to provide *sufficient evidence of carcinogenicity* when malignant neoplasms occur to an unusual degree with regard to incidence, site, type of tumour or age at onset, or when there are strong findings of tumours at multiple sites.

***Limited evidence of carcinogenicity*:** The data suggest a carcinogenic effect but are limited for making a definitive evaluation because, e.g. (a) the evidence of carcinogenicity is restricted to a single experiment; (b) there are unresolved questions regarding the adequacy of the design, conduct or interpretation of the studies; (c) the agent increases the incidence only of benign neoplasms or lesions of uncertain neoplastic potential; or (d) the evidence of carcinogenicity is restricted to studies that demonstrate only promoting activity in a narrow range of tissues or organs.

***Inadequate evidence of carcinogenicity*:** The studies cannot be interpreted as showing either the presence or absence of a carcinogenic effect because of major qualitative or quantitative limitations, or no data on cancer in experimental animals are available.

***Evidence suggesting lack of carcinogenicity*:** Adequate studies involving at least two species are available which show that, within the limits of the tests used, the agent is not carcinogenic. A conclusion of *evidence suggesting lack of carcinogenicity* is inevitably limited to the species, tumour sites, age at exposure, and conditions and levels of exposure studied.

(c) Mechanistic and other relevant data

Mechanistic and other evidence judged to be relevant to an evaluation of carcinogenicity and of sufficient importance to affect the overall evaluation is highlighted. This may include data on preneoplastic lesions, tumour pathology, genetic and related effects, structure–activity relationships, metabolism and toxicokinetics,

physicochemical parameters and analogous biological agents.

The strength of the evidence that any carcinogenic effect observed is due to a particular mechanism is evaluated, using terms such as 'weak', 'moderate' or 'strong'. The Working Group then assesses whether that particular mechanism is likely to be operative in humans. The strongest indications that a particular mechanism operates in humans derive from data on humans or biological specimens obtained from exposed humans. The data may be considered to be especially relevant if they show that the agent in question has caused changes in exposed humans that are on the causal pathway to carcinogenesis. Such data may, however, never become available, because it is at least conceivable that certain compounds may be kept from human use solely on the basis of evidence of their toxicity and/or carcinogenicity in experimental systems.

The conclusion that a mechanism operates in experimental animals is strengthened by findings of consistent results in different experimental systems, by the demonstration of biological plausibility and by coherence of the overall database. Strong support can be obtained from studies that challenge the hypothesized mechanism experimentally, by demonstrating that the suppression of key mechanistic processes leads to the suppression of tumour development. The Working Group considers whether multiple mechanisms might contribute to tumour development, whether different mechanisms might operate in different dose ranges, whether separate mechanisms might operate in humans and experimental animals and whether a unique mechanism might operate in a susceptible group. The possible contribution of alternative mechanisms must be considered before concluding that tumours observed in experimental animals are not relevant to humans. An uneven level of experimental support for different mechanisms may reflect that disproportionate resources have been focused on investigating a favoured mechanism.

For complex exposures, including occupational and industrial exposures, the chemical composition and the potential contribution of carcinogens known to be present are considered by the Working Group in its overall evaluation of human carcinogenicity. The Working Group also determines the extent to which the materials tested in experimental systems are related to those to which humans are exposed.

(d) Overall evaluation

Finally, the body of evidence is considered as a whole, to reach an overall evaluation of the carcinogenicity of the agent to humans.

An evaluation may be made for a group of agents that have been evaluated by the Working Group. In addition, when supporting data indicate that other related agents, for which there is no direct evidence of their capacity to induce cancer in humans or in animals, may also be carcinogenic, a statement describing the rationale for this conclusion is added to the evaluation narrative; an additional evaluation may be made for this broader group of agents if the strength of the evidence warrants it.

The agent is described according to the wording of one of the following categories, and the designated group is given. The categorization of an agent is a matter of scientific judgement that reflects the strength of the evidence derived from studies in humans and in experimental animals and from mechanistic and other relevant data.

Group 1: The agent is carcinogenic to humans.

This category is used when there is *sufficient evidence of carcinogenicity* in humans. Exceptionally, an agent may be placed in this category when evidence of carcinogenicity in humans is less than *sufficient* but there is *sufficient evidence of carcinogenicity* in experimental

animals and strong evidence in exposed humans that the agent acts through a relevant mechanism of carcinogenicity.

Group 2.

This category includes agents for which, at one extreme, the degree of evidence of carcinogenicity in humans is almost *sufficient*, as well as those for which, at the other extreme, there are no human data but for which there is evidence of carcinogenicity in experimental animals. Agents are assigned to either Group 2A (*probably carcinogenic to humans*) or Group 2B (*possibly carcinogenic to humans*) on the basis of epidemiological and experimental evidence of carcinogenicity and mechanistic and other relevant data. The terms *probably carcinogenic* and *possibly carcinogenic* have no quantitative significance and are used simply as descriptors of different levels of evidence of human carcinogenicity, with *probably carcinogenic* signifying a higher level of evidence than *possibly carcinogenic*.

Group 2A: The agent is probably carcinogenic to humans.

This category is used when there is *limited evidence of carcinogenicity* in humans and *sufficient evidence of carcinogenicity* in experimental animals. In some cases, an agent may be classified in this category when there is *inadequate evidence of carcinogenicity* in humans and *sufficient evidence of carcinogenicity* in experimental animals and strong evidence that the carcinogenesis is mediated by a mechanism that also operates in humans. Exceptionally, an agent may be classified in this category solely on the basis of *limited evidence of carcinogenicity* in humans. An agent may be assigned to this category if it clearly belongs, based on mechanistic considerations, to a class of agents for which one or more members have been classified in Group 1 or Group 2A.

Group 2B: The agent is possibly carcinogenic to humans.

This category is used for agents for which there is *limited evidence of carcinogenicity* in humans and less than *sufficient evidence of carcinogenicity* in experimental animals. It may also be used when there is *inadequate evidence of carcinogenicity* in humans but there is *sufficient evidence of carcinogenicity* in experimental animals. In some instances, an agent for which there is *inadequate evidence of carcinogenicity* in humans and less than *sufficient evidence of carcinogenicity* in experimental animals together with supporting evidence from mechanistic and other relevant data may be placed in this group. An agent may be classified in this category solely on the basis of strong evidence from mechanistic and other relevant data.

Group 3: The agent is not classifiable as to its carcinogenicity to humans.

This category is used most commonly for agents for which the evidence of carcinogenicity is *inadequate* in humans and *inadequate* or *limited* in experimental animals.

Exceptionally, agents for which the evidence of carcinogenicity is *inadequate* in humans but *sufficient* in experimental animals may be placed in this category when there is strong evidence that the mechanism of carcinogenicity in experimental animals does not operate in humans.

Agents that do not fall into any other group are also placed in this category.

An evaluation in Group 3 is not a determination of non-carcinogenicity or overall safety. It often means that further research is needed, especially when exposures are widespread or the cancer data are consistent with differing interpretations.

Group 4: The agent is probably not carcinogenic to humans.

This category is used for agents for which there is *evidence suggesting lack of carcinogenicity*

in humans and in experimental animals. In some instances, agents for which there is *inadequate evidence of carcinogenicity* in humans but *evidence suggesting lack of carcinogenicity* in experimental animals, consistently and strongly supported by a broad range of mechanistic and other relevant data, may be classified in this group.

(e) Rationale

The reasoning that the Working Group used to reach its evaluation is presented and discussed. This section integrates the major findings from studies of cancer in humans, studies of cancer in experimental animals, and mechanistic and other relevant data. It includes concise statements of the principal line(s) of argument that emerged, the conclusions of the Working Group on the strength of the evidence for each group of studies, citations to indicate which studies were pivotal to these conclusions, and an explanation of the reasoning of the Working Group in weighing data and making evaluations. When there are significant differences of scientific interpretation among Working Group Members, a brief summary of the alternative interpretations is provided, together with their scientific rationale and an indication of the relative degree of support for each alternative.

GENERAL REMARKS

This one-hundred-and-seventh volume of the *IARC Monographs* contains evaluations of the carcinogenic hazard to humans of exposure to polychlorinated biphenyls (PCBs) and polybrominated biphenyls (PBBs). The *IARC Monographs* programme has conducted several evaluations of the carcinogenicity of these agents (IARC, 1978, 1979, 1987; Table 1). At the meeting of the Advisory Group to Recommend Priorities for the IARC Monographs in 2008, PCBs were identified as an agent with high priority for re-evaluation (IARC, 2009). In the framework of the re-evaluation of 2,3,7,8-tetrachlorodibenzo-*para*-dioxin (TCDD) in October 2009 (IARC, 2012), the congener PCB-126 was upgraded to Group 1, and the Working Group recommended that there be an in-depth re-evaluation of agents with properties similar to TCDD (IARC, 2012). In February 2013, the *IARC Monographs* Working Group undertook a re-evaluation of PCBs and PBBs. A summary of the findings of this meeting appears in *The Lancet Oncology* (Lauby-Secretan *et al.*, 2013).

1. Considerations for definitions and nomenclature of PCBs and PBBs

Four decades after national governments began to ban their production and use, PCBs and PBBs remain a major concern to human health and the natural environment. Epidemiological studies in occupational settings generally studied workers exposed to the "fresh" product, by inhalation or dermal contact, while studies in the general population assessed individuals exposed primarily through intake of contaminated food, for which the exposure profile is difficult to assess. In contrast, experimental studies assessed individual congeners, combinations of a few congeners, or "fresh" commercial PCB products; however, none of these are identical to the PCB or PBB profiles to which people are exposed today. Indeed, most human exposure today is to complex mixtures originating from commercial products that have been altered by environmental processes (i.e. weathering, transport, and bioaccumulation).

The reason that PCB and PBB mixtures in the environment today differ from the original commercial products is that after release into the environment, the congener composition changes through partitioning, chemical transformation, and bioaccumulation. Partitioning refers to processes by which different congeners separate into air, water, sediment, and soil. Some congeners tend to volatilize or disperse as aerosols, providing an effective vehicle for long-range transport. Congeners with low chlorine or bromine content tend to be more volatile, and also somewhat soluble in water. Many congeners adsorb to organic materials in sediments and

Table 1 Historical overview of the *IARC Monographs* evaluations of PCBs and PBBs

Agent	Volume	Reference	Evidence in humans	Evidence in experimental animals	Mechanistic considerations	Group
PCBs	7	IARC (1974)	No formal evaluation	No formal evaluation	–	–
	18	IARC (1978)	No formal evaluation	No formal evaluation	–	–
	Suppl. 1	IARC (1979)	Inadequate	Sufficient	–	2B[a]
	Suppl. 4	IARC (1982)	Inadequate	Sufficient	–	2B
	Suppl. 7	IARC (1987)	Limited	Sufficient	–	2A
PCB-126	100F	IARC (2012)	–	Sufficient	Mechanistic upgrade	1

	41	IARC (1986)	Inadequate	Sufficient	No evidence for genotoxicity	–
	Suppl. 7	IARC (1987)	Inadequate	Sufficient	No evidence for genotoxicity	2B

[a] Possible target organs in humans identified as "skin (melanoma)" and "all sites"
PBB, polybrominated biphenyl; PCB, polychlorinated biphenyl

soils; adsorption tends to increase with chlorine or bromine content of the congener and with the organic content of the other material. Chemical transformation refers to the dechlorination or debromination of congeners. This can occur through photolysis, especially for some PBB congeners, or through interactions with bacteria. Chemical transformation is not synonymous with detoxication, as congeners having carcinogenic activity can be formed through dechlorination. Bioaccumulation occurs because PCBs and PBBs are absorbed by fish and other animals, and are highly soluble in lipids, while metabolism and elimination are relatively slower than absorption. Bioaccumulation through the food-chain tends to concentrate congeners of higher chlorine and bromine content.

The nomenclature of PCBs is complex. Publications often attempt to find dichotomies in these mixtures, or refer to PCBs in loose terms, such as:

- Higher and lower chlorinated
- Non-*ortho*, di-*ortho*, and similar terms
- Planar and non-planar
- Dioxin-like and non-dioxin-like
- Aryl hydrocarbon receptor-activating and non-activating
- High and low toxic equivalency (TEQ)
- Estrogenic and non-estrogenic
- Immunotoxic and non-immunotoxic.

The Working Group considered how to characterize the agents to be evaluated. The possibilities included:

- Specific congeners (e.g. PCB-126, PBB-153);
- Groupings of a small number of congeners (e.g. PCB-126 plus PCB-153);
- Commercial products (e.g. Aroclor 1242, Firemaster FF1);
- Large subsets of congeners (e.g. dioxin-like PCB congeners);
- PCBs or PBBs as a class.

Since human exposure always occurs to mixtures, the Working Group considered that it was appropriate to evaluate PCBs and PBBs each as a group.

2. Analysis of PCBs and PBBs

There are some difficulties in assessing and comparing PCB or PBB concentrations in any medium because of differences in analytical methods between laboratories, and differences in the numbers and types of congeners reported. Since there are 209 congeners, values reported

are rarely for true total PCB or PBB concentrations, but rather for a few selected congeners, or a "total" PCB or PBB concentration reported on the basis of analysis of a certain number of congeners only. Thus both the number and the specific congeners analysed must be considered when comparing results among studies. Another complication is that some authors present results for concentrations in total serum (usually called "wet weight"), while others report concentration in the lipid fraction of serum or other media (called "lipid adjusted"). The rationale for lipid adjustment is that these compounds are lipophilic, although there is some evidence that lipid adjustment poses risk of bias. Some investigators now report results as wet weight concentrations with serum lipids considered as a covariate. A further complication is that concentrations are reported in different units in different studies, and cannot always be directly compared.

Several biomarkers of exposure have been used as indicators of the internal dose or the body burden of PCBs or PBBs. These include measurement in blood (serum or plasma), adipose tissue, maternal or cord blood, breast milk and hair. In principle, blood lipid concentrations reflect recent exposures and the full spectrum of congeners to which a person is exposed, while the profile in adipose tissue reflects long-term intakes. However, recent exposure to less chlorinated congeners could result in higher non-equilibrium levels in the circulation. Levels in breast milk largely reflect the concentrations in adipose tissue.

A common theme with PCBs and PBBs is that major industrial accidents have resulted in unforeseeable human dietary exposure. In the 1968 Yusho incident in Japan, leaking Kanechlor 400 contaminated rice oil destined for human consumption. The 1979 Yucheng incident in Taiwan, China, also involved contamination of rice oil, this time by Kanechlor 500. And during 1973–1974, PBBs were unintentionally shipped as an animal feed supplement, contaminating milk, eggs, other dairy products, beef, pork, sheep, and chickens in Michigan, USA. Each incident involved relatively small amounts of PCBs or PBBs, but soon affected thousands of people. It should be noted that the effects of these incidents are not limited to cancer. The Yusho and Yucheng incidents also involved major effects on skin, such as severe chloracne, and recent studies have linked PBB exposure in Michigan to increased risks of spontaneous abortion, genitourinary conditions in male offspring, and suggestions of altered ovarian function.

3. Assessment of exposure to PCBs in epidemiological studies

Epidemiological studies investigating the potential carcinogenic effects of PCBs are basically of three types: occupational cohorts, environmental cohorts, and case–control studies. Most cohort studies were unable to quantify PCB exposures, although in some studies potential PCB exposure was estimated, or a qualitative scale was used. Within some cohort studies, more detailed analyses were achieved through nested case–control studies that collected additional information, sometimes including biomarkers, for specific subgroups of cancer cases and controls. Studies (nested case–control, and case–control) with biomarkers of exposure allow quantification of PCBs in serum or adipose tissue.

In this last group of studies, PCB exposure has been evaluated in a variety of ways: as to a group of congeners; as more or less specific commercial products; as specific PCB functional groupings; as specific combinations, such as PCB-118 + PCB-126; or as specific congeners.

There are several challenges in the interpretation and evaluation of the evidence for PCBs and cancer:

- In studies of workers and consumers of food items allegedly or known to have been "contaminated" with PCBs, it is usually not possible to determine the actual level of exposure.
- PCB exposure usually occurs to mixtures, and while these are often analysed as individual congeners in studies using biomarkers, many congeners are highly correlated and disentangling results for specific congeners is difficult.
- Several specific congeners are rarely or never included in epidemiological studies, primarily because they are excluded from "batch" gas chromatography analyses in many laboratories. Different studies focus on different PCBs; sometimes congeners are grouped and these groupings may differ across studies. Analytical results for specific congeners are best interpreted as markers for exposure to PCBs in general.
- In the occupational cohorts, the exposure route is usually dermal and inhalation, while in the environmental cohorts and case–control studies, the exposure route is usually ingestion (PCB exposure through diet).
- A few environmental studies refer to acute exposures (accidents), while most studies refer to long-term exposures (occupational exposure, and contamination of diet) and long-term consequences of accidents.
- Latency considerations are usually not possible when using biomarker samples collected long after exposure. This may be a cause for concern in interpreting findings on less persistent lower-chlorinated PCBs, but it would be less so for the persistent highly chlorinated PCBs.
- In principle, the use of biomarkers should reduce exposure-measurement error; studies evaluating biomarkers for many PCB congeners tend to generate multiple comparisons, potentially increasing the number of false-positive associations.
- Sampling may be problematic when adjusting plasma or serum measurements by lipid content, because of lipid degradation in samples. Most cohort studies could not take into account relevant confounders, while some of these were considered in the nested case–control and case–control studies.
- Very few studies have addressed interaction or effect modification with other environmental exposures such as tobacco smoke and other chemicals.

4. Genotoxicity of PCBs

Many early tests for genotoxicity with PCBs, performed 10 years ago or more, reported negative results. However, almost all of these studies are not suited for hazard assessment, primarily due to the low doses tested and, in case of studies in vitro, the lack of an exogenous metabolic system. If retested with metabolic activation, many PCB congeners would show genotoxicity. Most PCB mixtures and the few congeners that were tested gave negative results in the Ames test with and without metabolic activation [reviewed in (Silberhorn *et al.*, 1990; Ludewig, 2001)]. A negative result in the Ames test is not uncommon for compounds with complicated and multistep activation pathways such as that proposed for less chlorinated PCBs, i.e. metabolic activation to quinones. Thus a bacterial test for mutagenicity is probably not an appropriate assay for evaluating the genotoxicity of PCBs.

5. The pleiotropic carcinogenicity of PCBs

In experimental animals, commercial PCB mixtures and some individual congeners are complete carcinogens, producing neoplastic

lesions primarily in the liver (hepatocytes and biliary tract); however, benign and malignant tumours have also been observed in many other organs of the treated animals (lung, oral mucosa, thyroid gland, uterus, skin, and the mammary gland in the offspring of treated mothers).

Accidental release of PCBs into food in Taiwan, China, and in Japan, has led to acute and chronic PCB toxicity in thousands of people. Examination of the mortality rate of the Yusho victims in Japan 40 years after the event revealed an increased risk of all types of cancer combined, cancers of the liver and lung in men, and cancer of the liver in women (Onozuka *et al.*, 2009). A similar 24-year follow-up study of Yucheng victims in Taiwan, China, found increased mortality from liver disease, but no increase in risk of cancer of the liver (Tsai *et al.*, 2007). After reviewing all epidemiological studies on occupational and environmental exposure to PCBs, the Working Group concluded that there was *sufficient evidence* of carcinogenicity in humans, on the basis of an increased risk of malignant melanoma; one study found a significant association with uveal melanoma in exposed workers. In addition, increased risks were seen in some studies between exposure to PCBs and non-Hodgkin lymphoma, and for cancer of the breast in some subgroups of women. Positive findings were observed in individual studies for cancers of the brain, prostate, stomach, and pancreas.

PCBs bioaccumulate in fatty tissue, so higher marine mammals are particularly exposed. Reports of cancers in marine wildlife living in areas with high measured PCB concentrations provide another source of cancer data. For example, a large cell immunoblastic lymphoma in a bottlenose dolphin (*Tursiops truncates*) with high blood PCB concentrations (Jaber *et al.*, 2005); uterine leiomyomas in 257 female Baltic grey seals (*Halichoerus grypus*) (Bredhult *et al.*, 2008); and undefined carcinomas in 38 stranded wild California sea lions (*Zalophus californianus*), which were reported to be strongly associated with high PCB concentrations measured in the animals (Ylitalo *et al.*, 2005).

6. Toxicity and carcinogenicity of PBBs

The Working Group also considered the evidence on carcinogenicity of PBBs. The chemical structure of PBBs resembles that of PCBs, with substitution by bromine rather than chlorine atoms. PBBs were used primarily as flame retardants in the 1970s, but production has been discontinued in most countries for many years. Following the accidental release of PBBs in Michigan, USA, the one study that investigated cancer reported adjusted odds ratios of up to 23-fold for cancer of the digestive system and up to 33-fold for lymphoma, with an exposure–response trend across exposure groups. This study included cancer results until 1993; the study has not yet been updated to include cancers that have occurred during the subsequent 20 years. Concerning experimental and mechanistic studies, while there is an extensive body of literature on the carcinogenicity of PCBs, their brominated analogues have received much less attention and study. PBBs will likely be found to exhibit their toxicity and disease potential via many of the same pathways as their chlorinated counterparts, with equivalent or greater toxicity.

The information contained in this volume has contributed to the report "Health risks of PCB in the indoor climate in Denmark," published by the Sundhedsstyrelsen (Danish Health and Medicines Authority, 2013) and was considered during the evaluation of non-dioxin like PCBs by the Joint FAO/WHO Expert Committee on Food Additives (June 2015).

POLYCHLORINATED BIPHENYLS

1. EXPOSURE DATA

1.1 Identification of the agent

1.1.1 Nomenclature

Polychlorinated biphenyls (PCBs) are a class of aromatic chemical compounds in which some or all hydrogen atoms attached to the biphenyl ring are substituted by chlorine atoms (m + n = 1–10) (Fig. 1.1). Synonyms for PCBs include chlorinated biphenyls, chlorinated diphenyls, chlorobiphenyls, or polychlorobiphenyls.

The general chemical formula is $C_{12}H_{(10-m-n)}Cl_{(m+n)}$, where (m + n) is the number of chlorine atoms on the two rings. Depending on the position and number of the chlorine atoms, there are theoretically 209 individual PCB compounds (congeners). The carbon positions are numbered 1 to 6 on one ring, and 1′ to 6′ on the other. While positions 2,2′,6, and 6′ are called "*ortho*," positions 3,3′,5 and 5′ are named "*meta*" and positions 4 and 4′ are called "*para*."

Two different but correlated nomenclature systems are currently used. According to the International Union of Pure and Applied Chemistry (IUPAC) and in particular rule A-52.3 related to hydrocarbon systems, an unprimed number is considered lower (higher priority) than the same number when primed. Assemblies of unprimed and primed numbers are arranged in ascending numerical order. For a given PCB congener, the name lists the numbers sequentially [e.g. the PCB congener with chlorines on carbons 2,4,5, and 3′,4′ is identified as 2,3′,4,4′,5 (and not 2′,3,4,4′,5′)]. A deviation in that system lists the unprimed and primed chlorinated ring positions separately, sometimes eliminating the prime symbols and the commas for clarity and ease of typing (e.g. 245–3′4′5′ or 245–345).

In an additional strategy proposed by Ballschmiter & Zell (1980), a number (called "BZ number") is attributed to each individual congener. This number correlates the structural arrangement of the PCB congener and ascending order of number of chlorine substitutions within each sequential homologue (Ballschmiter & Zell, 1980). This results in the congeners being numbered from PCB-1 to PCB-209. This shorthand nomenclature has become quite popular and is convenient for many uses, although it is important to note that it obscures the chemical identity of the congener and does not strictly follow the IUPAC rules.

Slight changes in the original BZ congener-numbering system were later recommended to correct some errors (Schulte & Malisch, 1983; Ballschmiter *et al.*, 1992), and this resulted in the renumbering of BZ numbers 199–201. Guitart *et al.* (1993) used a computer program to systematically renumber the PCBs according to the strict IUPAC rules. As a result, they recommended that the congeners previously numbered 107, 108, 109, 199, 200, and 201 be renumbered 109, 107, 108, 200, 201, and 199, respectively (reviewed in Mills *et al.*, 2007). The nomenclature for PCB congeners based on this report is shown in Table 1.1 and will be preferred in this *Monograph*. However, in the scientific literature,

[a] Revised PCB numbering system, including the revised numbering of congeners 107–109 and 199–201. For several PCB congeners, the indicated (truncated) structural names do not strictly adhere to the IUPAC rules (primed and unprimed numbers are interchanged). A comprehensive review of PCB nomenclature, including IUPAC names, is given in Mills *et al.* (2007).

[b] Dioxin-like PCBs are indicated in bold type

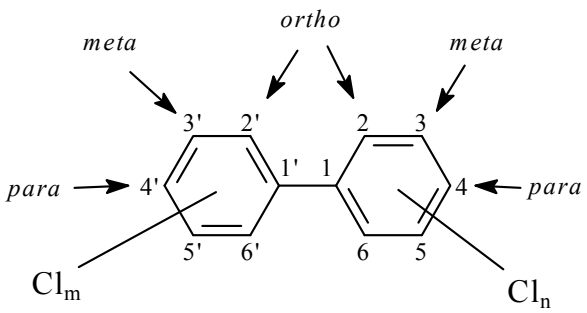
Fig. 1.1 Chemical structure of PCBs and the IUPAC numbering system



Hydrogen atoms in positions 2,2′,6,6′ (*ortho*), 3,3′,5,5′ (*meta*) and/or 4,4′ (*para*) may be substituted by chlorine atoms; (m + n) is the number of chlorine atoms on the two rings
IUPAC, International Union of Pure and Applied Chemistry; PCB, polychlorinated biphenyl

the revised numbering of congeners 107–109 has not been adopted systematically; the numbering system commonly used has been that proposed by Ballschmiter *et al.* (1992) where only the original BZ numbers 199–201 are changed.

PCBs can be categorized by degree of chlorination (number of chlorine atoms) in 10 homologue groups (Table 1.2) from monochlorobiphenyls to decachlorobiphenyls. More than 60% of the PCBs are tetra- to hexachlorophenyls.

In the biphenyl molecule, the two aromatic rings can rotate about the connecting single 1,1′-bond (Fig. 1.1). As with all molecules, there is a low-energy preferred conformation. With PCBs, this conformation is dependent on the degree of chlorine substitution, since chlorine is larger than hydrogen and creates more steric hindrance to the rotation (Erickson, 2001). The two extreme theoretical configurations are "planar" or "coplanar," in which the two benzene rings are in the same plane, and "non-planar" in which the benzene rings are at a 90° angle to each other (Faroon *et al.*, 2000). The probability of attaining a planar configuration is essentially determined by the number of substitutions in the *ortho* positions (2,2′,6,6′): the benzene rings of non-*ortho* substituted PCBs as well as mono-*ortho* substituted PCBs can assume a planar configuration and are referred to as "planar" or "coplanar" congeners (Erickson, 1997). The replacement of hydrogen atoms in the *ortho* positions with larger chlorine atoms forces the aromatic rings to rotate out of the planar configuration (Fig. 1.2); such structures are referred to as "non-planar" or "non-coplanar" congeners. [The Working Group does not recommend the use of this terminology, which is not technically appropriate since these PCBs do not easily assume a planar conformation.]

The relationship between PCB congener number and the Chemical Abstracts Service (CAS) registry number is given in Table 1.3. The congener numbering presented in this table follows that in Table 1.1, with the revised numbering of congeners 107–109. The congener lipophilicity is given in the same table, and was expressed against capacity to partition in octanol and water (K_{ow}) (see Section 1.1.2). Congeners can also be characterized by descriptors (CP0, CP1, 4Cl, PP, 2M) that give rapid access to geometry and substituent positions. The first descriptor, CP0, characterizes 20 congeners that are referred to as non-*ortho* congeners, consisting of those with chlorine substitution at none of the *ortho* positions on the biphenyl backbone. The second descriptor, CP1, comprises 48 congeners that are referred to as mono-*ortho* congeners and include those with chlorine substitution at only one of the *ortho* positions; CP0 and CP1 congeners can adopt a planar configuration. The 4Cl descriptor designates 169 congeners that have a total of four or more chlorine substituents, regardless of position. There are 54 PP congeners that have both *para* positions chlorinated. The 2M group contains 140 congeners that have two or more of the *meta* positions chlorinated. A total of 11 congeners have no descriptor.

The twelve congeners that display all descriptors are referred to as "dioxin-like" (Table 1.4). These twelve PCBs, namely PCB-77, PCB-81, PCB-105, PCB-114, PCB-118, PCB-123, PCB-126, PCB-156, PCB-157, PCB-167, PCB-169, and

Table 1.2 Physical and chemical properties of PCBs according to homologue group

Homologue group	CAS No.	Formula	No. of isomers	BZ No.	Relative molecular mass	Chlorine (% w/w)	Vapour pressure (Pa at 25 °C)[a]	Melting point (°C)[b]	Boiling point (°C)[c]

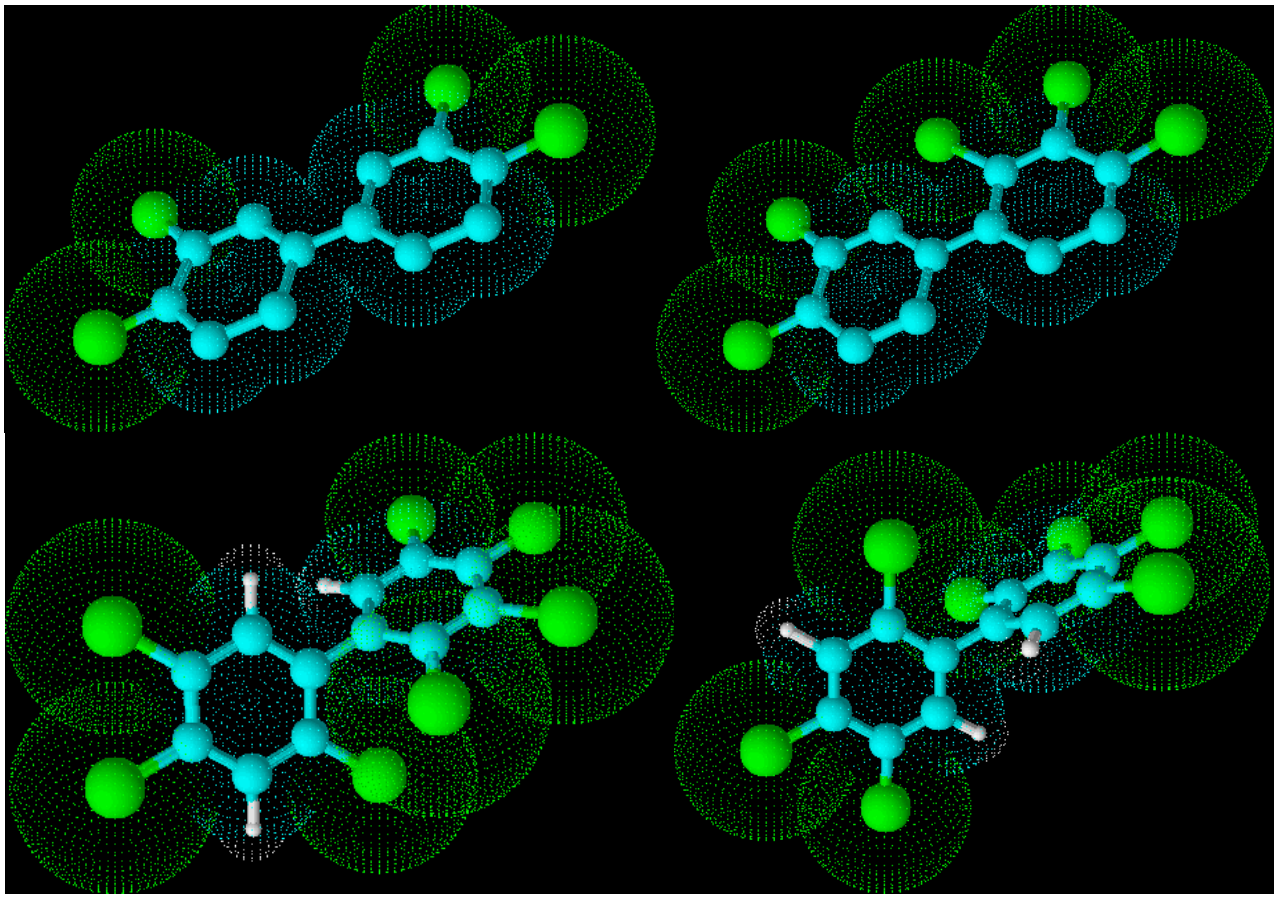
Fig. 1.2 Tridimensional chemical structures of selected PCBs



Upper panel: Spatial configuration of two dioxin-like PCBs: PCB-77 (3,3′,4,4′-tetrachlorobiphenyl), a non-*ortho* congener (left), and PCB-105 (2,3,3′,4,4′-pentachlorobiphenyl), a mono-*ortho* congener (right)
Lower panel: Spatial configuration of two di-*ortho* PCBs: PCB-153 (2,2′,4,4′,5,5′-hexachlorobiphenyl; left) and PCB-180 (2,2′,3,4,4′,5,5′-heptachlorobiphenyl; right)
Courtesy of Professor B. LeBizec

PCB-189, have been assigned toxicity equivalency factors (TEFs, assigned by WHO in 1998 and revised in 2005) (Van den Berg *et al.*, 2006). [The Working Group stressed that the activities of these PCB congeners are not solely dioxin-like.]

Depending on the context of the study or investigation, specific congeners may be monitored. For instance, the Stockholm Convention on Persistent Organic Pollutants (POPS) recommends measurement of six indicator PCBs (PCB-28, PCB-52, PCB-101, PCB-138, PCB-153, and PCB-180) to characterize contamination by PCBs. These congeners were chosen because they are found at higher concentrations in the environment, in food, or in human fluids/tissues. Depending on country and context, different lists of varying numbers of congeners may be used, e.g. 36 congeners for the Centers for Disease Control and Prevention, USA, or only PCB-138, PCB-153, and PCB-180 most frequently in epidemiological studies with human blood (see Section 2).

Of the 209 PCB congeners, 78 display axial chirality. Only 19 of these congeners, those with three or more chlorine atoms in the *ortho* position, exist as two mirror-image atropisomers, i.e. two chiral atropisomers (Lehmler & Robertson,

[a] The nomenclature in this table adheres to the IUPAC rules and thus primed and unprimed numbers may be interchanged compared with Table 1.1. Please see text for more details.

[b] Congener descriptors (CP0, CP1, 4Cl, PP, 2M) have been given where relevant; they give rapid access to geometry and substituent positions. 68 coplanar congeners fall into one of two groups CP0 or CP1.

The first group of 20 congeners consists of those without chlorine substitution at any of the "*ortho*" positions on the biphenyl backbone and are referred to as CP0 or non-"*ortho*" congeners. The second group of 48 congeners includes those with chlorine substitution at only one of the "*ortho*" positions and are referred to as CP1 or mono-"*ortho*" congeners. 175 congeners have a total of four or more chlorine substituents, regardless of position (4Cl). 54 congeners have both "*para*" positions chlorinated (PP). 146 congeners have two or more of the "*meta*" positions chlorinated (2M). The twelve congeners that have all four of the congener descriptors are referred to as being "dioxin-like," and are indicated in bold type.

In ATSDR (2000), PCB-63 was mistakenly attributed the CAS number of a pentachlorobiphenyl; for Henry's law constants, vapour pressure and solubility of most individual congeners, the reader is referred to Dunnivant & Elzerman (1988) and references within.

[c] Vapour pressures have been indicated for a selection of individual congeners.

From Van den Berg *et al.* (1998, 2006)

2001; Kania-Korwel & Lehmler, 2013). The IUPAC nomenclature and BZ number for the 19 atropisomeric PCBs are listed in Table 1.5. They are stereoisomers resulting from hindered rotation around single bonds where the steric-strain barrier to rotation is high enough to allow for the isolation of the enantiomers (Haglund & Wiberg, 1996; Harju & Haglund, 1999). Both atropisomers have the same chemical and physical behaviour, except for optical rotation (Lehmler *et al.*, 2010). They are stable at 25 °C, but at elevated temperatures it is necessary to separate the enantiomers via high-resolution chiral gas chromatography (GC) (Schurig & Reich, 1998; Harju & Haglund, 1999).

1.1.2 Chemical and physical properties of PCBs

Pure single PCB congeners are mostly colourless or slightly yellowish, often odourless, crystalline compounds. Commercial products, however, are viscous liquid mixtures of these compounds, with viscosity increasing with degree of chlorination, and colour ranging from light yellow to a dark colour. For example, Aroclor 1242 is a "mobile liquid" and Aroclor 1260 is a "sticky resin" (Erickson, 2001). These products do not crystallize at low temperatures, but turn into solid resins. An important property of PCBs is their general inertness; they resist acids, alkalis and oxidants and are fire-resistant because of their high flash-points (IPCS, 2003). However, under certain conditions, they may be destroyed by chemical, thermal and biochemical processes. PCBs show excellent dielectric (insulating) properties. This has made them useful in a wide variety of applications, including as dielectric fluids in transformers and capacitors, heat-transfer fluids, and lubricants.

The physical properties of PCBs are important in understanding their analytical, physiological, and environmental properties. However, the interactions of the various physical properties can be extremely complex (Erickson, 2001). Chemical and physical properties such as solubility, vapour pressure, and Henry's law constant have been reported for individual congeners (Shiu & Mackay, 1986; Murphy *et al.*, 1987; Sabljić & Güsten, 1989; Dunnivant *et al.*, 1992; Falconer & Bidleman, 1994). Data for homologue groups and for a selection of PCBs are presented in Table 1.2,

Table 1.5 PCB congeners that exist as chiral atropisomers

PCB	IUPAC name
PCB-45	2,2′,3,6-TetraCB
PCB-84	2,2′,3,3′,6-PentaCB
PCB-88	2,2′,3,4,6-PentaCB
PCB-91	2,2′,3,4′,6-PentaCB
PCB-95	2,2′,3,5′,6-PentaCB
PCB-131	2,2′,3,3′,4,6-HexaCB
PCB-132	2,2′,3,3′,4,6′-HexaCB
PCB-135	2,2′,3,3′,5,6′-HexaCB
PCB-136	2,2′,3,3′,6,6′-HexaCB
PCB-139	2,2′,3,4,4′,6-HexaCB
PCB-144	2,2′,3,4,5′,6-HexaCB
PCB-149	2,2′,3,4′,5′,6-HexaCB
PCB-171	2,2′,3,3′,4,4′,6-HeptaCB
PCB-174	2,2′,3,3′,4,5,6′-HeptaCB
PCB-175	2,2′,3,3′,4,5′,6-HeptaCB
PCB-176	2,2′,3,3′,4,6,6′-HeptaCB
PCB-183	2,2′,3,4,4′,5′,6-HeptaCB
PCB-196	2,2′,3,3′,4,4′,5,6′-OctaCB
PCB-197	2,2′,3,3′,4,4′,6,6′-OctaCB

CB, chlorinated biphenyl; IUPAC, International Union of Pure and Applied Chemistry; PCB, polychlorinated biphenyl

Table 1.3, and Table 1.6. Melting points range from 25 °C (PCB-2, PCB-7 and PCB-9) to 306 °C (PCB-209). Boiling points increase from low (monochlorobiphenyl, 285 °C) to highly (decachlorobiphenyl, 456 °C) chlorinated congeners (Hutzinger *et al.*, 1974; Shiu & Mackay, 1986).

The solubility of PCBs in water is extremely low, ranging from an average of 0.0012 to 4830 µg/L for the chlorobiphenyl congeners that occur commonly. The high solubility of the *ortho*-chlorinated congeners (4.8 mg/L for PCB-1) may be due to hydrogen bonding associated with the more polar character of these molecules. Solubility decreases rapidly in *ortho*-vacant congeners, especially as the *para* positions are filled, which may result in greater and more uniform perimeter electronegativity and interference with hydrogen bonding. PCBs are freely soluble in non-polar organic solvents, oils and biological lipids, and the shift from water to lipid solubility is linked to the degree of chlorination (Hutzinger *et al.*, 1974; Shiu & Mackay, 1986; ATSDR, 2000; IPCS, 2003).

The octanol/water partition coefficient (K_{ow}) is defined as the ratio of a chemical's concentration in the octanol phase to its concentration in the aqueous phase of a two-phase octanol/water system; values of K_{ow} are thus unitless (Table 1.3 and Table 1.6). The reported log K_{ow} values have been reviewed by Shiu & Mackay (1986). Fig. 1.3 shows the remarkable correlation between log K_{ow} (lipophilicity) and number of chlorine atoms (BZ numbers); log K_{ow} values ranged from 4.5 to 8.3. This partitioning plays a key role in environmental fate and transport. PCBs tend to favour the non-polar phase and will partition away from water to most solids, the organic portion being the preferred site (Erickson, 2001).

PCBs are characterized by Henry's law constants [a measure of the equilibrium distribution coefficient between air and water] that tend to decrease with a higher degree of chlorination. Less chlorinated PCB congeners have a considerably higher vapour pressure (1–2 Pa at 25 °C for monochlorobiphenyls) than the more highly chlorinated congeners (1.4×10^{-6} Pa for decachlorobiphenyl) (Shiu & Mackay, 1986). Therefore, the composition in air is dominated by the less chlorinated congeners and atropoisomers.

At high temperatures, PCBs are combustible, and the products of combustion include polychlorinated dibenzofurans (PCDFs) and hydrogen chloride, and polychlorinated dibenzodioxins (PCDDs) (IPCS, 1993; ATSDR, 2000).

Photochemical degradation may be one route for the breakdown of PCBs in the environment: photochemical experiments conducted under simulated natural conditions on several pure chlorobiphenyls and on commercial PCB products have indicated several degradative reactions, such as dechlorination, polymerization and solvolysis.

Table 1.6 Physical and chemical data for a selection of PCB congeners

PCB	No. of chlorine atoms	Melting point (°C)	Boiling point (°C)	Vapour pressure (10^{-6} kPa at 25 °C)	Log K_{ow}	Water solubility (µg/L)
PCB-1[a]	1	34	274	184	4.5	4830 (25 °C)

1.1.3 *Trade names and composition of commercial products*

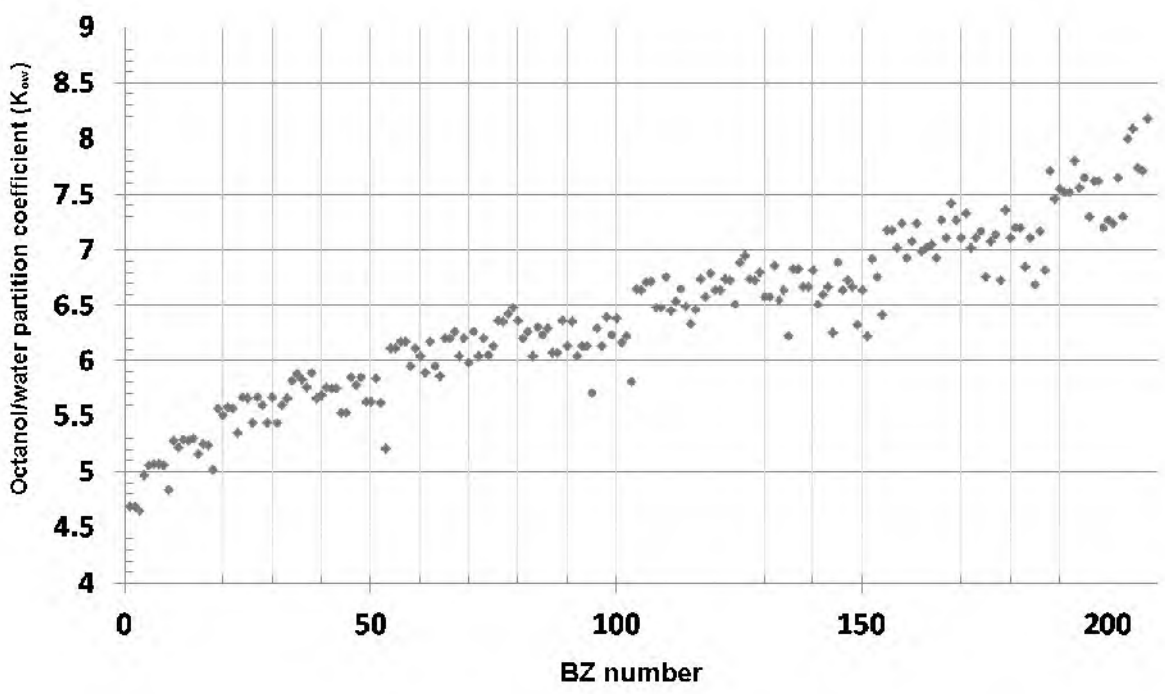
PCBs have never been used as single compounds, but rather as complex mixtures. The commercial products were manufactured to yield a certain degree of chlorination to fulfil technical requirements, generally between 21% and 68% chlorine.

Trade names for commercial products are given in Table 1.7. The most well known are Aroclor, Clophen, Phenochlor, Kanechlor, Pyralene, Fenclor, and Delor. The Aroclors, which were manufactured in the USA, are identified by a four-digit numbering code in which the first two digits indicate the type of mixture and the last two digits indicate the approximate chlorine content by percentage weight. Thus Aroclor 1242 is a chlorinated biphenyl mixture with an average chlorine content of 42%. The exception to this code is Aroclor 1016, which has an average chlorine content of 41% (Hutzinger *et al.*, 1974). Similarly, the Kanechlors are identified by a three-digit value indicating the average chlorine content (300 for 30%). Other products of similar chlorination content have been produced by different companies in Europe, Japan, and China.

Table 1.8 indicates equivalencies between main commercial formulations of PCBs. [The Working Group noted that these should be considered as approximate.] Since different production yield slight differences in the congener mixture, mixtures with comparable chlorine content but from different manufacturers (e.g. Aroclor 1260 and Clophen A60) show varying compositions, although with strong similarities (Johnson *et al.*, 2000).

The homologue composition of the commercial PCB products varies greatly according to chlorination degree achieved (Table 1.9). For example, Aroclor 1242 is a mixture of mono- to heptachlorobiphenyls, while Aroclor 1260 contains penta- to octachlorinated homologues. The concentrations of single congeners within each homologue group also differ between different products and batches (Fig. 1.4). About 130 of the 209 congeners have been identified in commercial formulations at concentrations above 0.05%. Generally, commercial PCB products consist of about 100–140 PCB congeners, with mono- and non-*ortho* substituted PCBs as minor or trace constituents (Frame *et al.*, 1996a, b; Johnson *et al.*, 2000).

Fig. 1.3 Octanol/water partition coefficient (K_{ow}) of PCB congeners according to the degree of chlorination (BZ number)



BZ, Ballschmiter and Zell; PCB, polychlorinated biphenyl
Compiled by the Working Group

An archetypal distribution of PCB congeners was detected in Aroclor 1254, lot 124–191 (corresponding to the historical G4 production process), while lot 6024 showed a profile characteristic of the A4 production process used between 1974 and 1976 (Kodavanti *et al.*, 2001). Indeed, Aroclor 1254 was produced by two different chlorination procedures (two-step versus single-step chlorination) (Frame *et al.*, 1996a, b). The differences in composition of the two lots are given in Table 1.10. Although Aroclor 1254 A4 probably represented less than 1% of the total production of Aroclor 1254, this PCB product was extensively used by standard suppliers and thus by researchers (Frame, 1999).

Chiral PCB congeners are important constituents of both technical and environmental mixtures of PCBs. For example, the total concentration of chiral PCB congeners in the commercial mixtures Aroclor 1242 and Aroclor 1260 is 6% and 30% by weight, respectively (Kania-Korwel *et al.*, 2007). Chiral enantiomers may have different biological and toxicological properties (Püttmann *et al.*, 1989; Rodman *et al.*, 1991). There is evidence that PCB atropisomers differ in their biological activities (Kania-Korwel *et al.*, 2006, 2008). They have been found in non-racemic proportions in many species (Lehmler *et al.*, 2010; Wong & Warner, 2009). While physical and chemical processes in the environment generally affect the two enantiomers of a known compound at the same rate, biological processes may result in the enrichment of one of the enantiomers, because of enantio-selective interactions with biological macromolecules (Buser & Mueller, 1993).

1.1.4 *Contaminants and impurities of commercial products*

Commercial PCB products have been reported to be contaminated with other chlorinated aromatic compounds, such as polychlorinated naphthalenes and PCDFs (IARC, 1978). Vos & Koeman (1970) were able to identify tetrachlorodibenzofurans, pentachlorodibenzofurans, and chlorinated naphthalenes in samples of Phenoclor DP-6 and Clophen A60. Bowes *et al.* (1975) examined samples of Aroclor 1248, 1254 and 1260 produced in 1969, samples of Aroclor 1254 from 1970 and Aroclor 1016 from 1972, and samples of Aroclor 1260, Phenoclor DP-6 and Clophen A60. They found PCDFs in all Aroclor preparations except Aroclor 1016, and in Clophen A60 and Phenoclor DP-6 (Table 1.11). The levels of PCDFs were in the low microgram per gram range (Erickson, 2001), but additional PCDFs may be formed from PCBs on heating. Impurities such as 2,3,7,8-tetrachlorodibenzofuran and 2,3,4,7,8-pentachlorodibenzofuran have been reported in different amounts under various manufacturing conditions in Aroclor 1248, Aroclor 1254, Clophen A-60, Phenoclor DP-6, and Kanechlor 400 (de Voogt & Brinkman, 1989). Rappe & Gara (1977) confirmed by capillary gas chromatography–mass spectrometry (GC–MS) that 2,3,7,8-tetrachlorodibenzofuran was one of the main PCDFs in "Yusho oil," as reported by Nagayama *et al.* (1976).

The proportion of impurities may vary between batches. For example, Aroclor 1254 with lot numbers 6024 and 124–191, which were produced by the same company by two different production processes, showed a 3.4-fold difference in the total concentration of PCDFs (Table 1.10).

It is important to note that PCDDs are not found in commercial PCB preparations (Erickson, 2001).

Overall, differences in composition as well as the presence of toxicologically relevant impurities may have had a significant impact on the results of toxicological studies with commercial

PCB products and mixtures (EFSA, 2005). Consistent interpretation of the results of such studies, especially differentiation of the effects caused by respective PCBs, may only be achieved if the congener composition of these mixtures is known. The determination of the content in specific congeners was not feasible in most cases due to the lower sensitivity of analytical techniques available in the past.

1.2 Analysis

1.2.1 General considerations

Past and current methods for the chemical analysis of PCBs have been reviewed recently (Le Bizec *et al.*, 2015). Since the 1960s, PCBs have been determined using GC techniques with electron capture detection (ECD), initially using packed columns. Today the separation has been improved by the use of capillary columns and the selectivity by the use of MS detectors. Increase in sensitivity, expressed as decreasing detection limits, has been achieved as analytical techniques have improved.

Originally, PCB concentrations were determined on the basis of commercial products, e.g. various Aroclor products with different chlorination levels. Later, PCB concentrations were determined based on homologue groups, while today congener-specific analysis is a common practice. These methodological changes, including differences in the basis of quantification, are an obstacle when comparing older with more recent studies.

Even when comparing studies from the same period, it can be difficult to compare PCB concentrations reported by different laboratories, if information on data quality is not available and if the results for different numbers of congeners are summarized. Often "total" PCB concentrations are reported, summing up all the congeners included in the laboratory's method and assumed to approach the true total PCB concentration. Operational sum parameters have been defined to harmonize congener lists and improve comparability, for example, the six indicator PCB congeners (PCB-28, PCB-52, PCB-101, PCB-138, PCB-153, and PCB-180), expressed as PCB_6. The six congeners were not selected from a toxicological point of view, but were considered as indicators for the different PCB patterns in various sample types and are most suitable for evaluating non-dioxin-like PCBs (NDL-PCBs) (EFSA, 2005). This parameter is used, for example, in the European food and feed regulation (EC, 2011a).

Some agencies, such as the International Council for the Exploration of the Sea (ICES), recommend reporting PCB_7, which includes the

mono-*ortho* congener PCB-118 in addition to the PCB_6 (ICES, 2012; Webster *et al.*, 2013). In the Arctic Monitoring and Assessment Programme (AMAP), the sum of 10 PCB congeners is often reported (PCB-28, PCB-31, PCB-52, PCB-101, PCB-105, PCB-118, PCB-138, PCB-153, PCB-156, PCB-180), which includes the six indicator PCBs. However, reports of individual concentrations in scientific studies have the advantage of allowing sum calculations as required. In food analyses, PCB concentrations are preferred to compliance/non-compliance reports (EFSA, 2005).

Depending on the sample type and the purpose of the study, PCB concentrations may be reported in different units. Concentrations in solid samples are generally reported in mass per mass. Normalizations to dry weight or lipid weight are common for abiotic matrices (e.g. soil and sediment) and those with a high lipid content (e.g. fatty food products), respectively. For liquid and air samples, the concentrations are often given in mass per volume. However, as liquid volumes are susceptible to small changes during sample storage and cannot be determined as precisely as masses, concentrations in small liquid volume samples (e.g. blood) are increasingly related to mass instead of volume.

Apart from the adjustment of mass for fresh weight (also referred to as raw weight, wet weight), lipid normalization of PCB concentrations in blood samples is also common. (Schisterman *et al.*, 2005; Phillips *et al.*, 1989; Grimvall *et al.*, 1997). [The Working Group has acknowledged that a variety of lipid determination methods for blood are used and that there is no consensus on how to determine lipid concentrations.]

Given the low concentrations of PCBs in some matrices, reliable quality assurance and quality control are particularly important, including for example monitoring of recovery rates and procedural blanks, duplicate analyses, analyses of in-house reference material and external quality control in proficiency testing schemes.

The transport and storage of samples can be a source of error through PCB loss or contamination. Studying the effects of storage conditions on PCBs in biological material, De Boer & Smedes (1997) generally did not find temperature effects as long as the temperature was < 5 °C, or downward trends in PCB contents. Practical guidance on the storage and transport of marine samples intended for PCB analysis is given by OSPAR (1999, 2002) and Webster *et al.* (2013).

[The Working Group stressed the importance of how the "non-detects" were reported and treated in the data analysis. There are a variety of methods used and there is currently no global consensus.]

1.2.2 Analytical tools

Instrumental analysis is essentially identical for all matrices. Dioxin-like PCBs (DL-PCBs) are often analysed together with dioxins and furans by gas chromatography-high resolution mass spectrometry (GC-HRMS). For this purpose, DL-PCBs are separated from other PCB congeners as part of the clean-up and fractionation process, for example using activated carbon, porous graphite columns, or 2-(1-pyrenyl) ethyldimethylsilyated (PYE) silica (Hess *et al.*, 1995).

Gas chromatography-electron capture detection (GC-ECD) provides low detection limits and high precision, but is less specific than MS, as it separates PCB congeners only by retention time. MS adds a second dimension in terms of different mass spectra. Therefore, ^{13}C-labelled PCB congeners can be separated from the native molecule on a mass basis. In contrast, as retention times are identical to the native analogues, ^{13}C-labelled PCB congeners cannot be used in GC-ECD analyses.

Due to lower selectivity and the risk of interference, GC-ECD is often based on two GC capillary columns of different polarity (dual column GC) (Covaci & Schepens, 2001). Webster

et al. (2013) recommend that retention times be checked for shifts between analytical runs, usually with the help of characteristic peaks, for example those added as injection standards. Coelution of PCB-138 and PCB-163 occurs on many common capillary columns.

Among the MS techniques, electron capture negative ionization (ECNI) is very sensitive for detection of penta- to decachlorinated PCBs (Webster *et al.*, 2013). However, electron impact (EI) has better selectivity than ECNI and comparable sensitivity when combined with large-volume injection, which requires rigorous sample clean-up (Covaci *et al.*, 2002a). Suitable target and qualifier ions for PCBs are listed by Webster *et al.* (2013).

Some studies have applied gas chromatography-ion trap mass spectrometry (GC-ITMS), for example for the analysis of PCBs in human milk (Gómara *et al.*, 2011). GC-ITMS with its MS/MS option offers increased selectivity while being less expensive than HRMS (Webster *et al.*, 2013). Triple quadrupole mass spectrometry (LRMS/MS) operated in the selected reaction monitoring mode has also been shown to provide selectivity and sensitivity comparable to that of HRMS in food analyses (Ingelido *et al.*, 2012).

Bioassays are an alternative method of determining PCB concentrations and have been suggested as screening tools for monitoring PCDD/Fs and DL-PCBs in foodstuffs by the European Commission Directive 2002/69 (EC, 2002). The dioxin-responsive chemically activated luciferase (CALUX or lux) assay is mechanism-specific and uses the interaction with the aryl hydrocarbon (Ah) receptor. Differences between results of the bioassay and of the conventional targeted high resolution gas chromatography-high-resolution mass spectrometry (HRGC-HRMS) analysis of PCDD/Fs and DL-PCBs have been shown (van Leeuwen *et al.*, 2007), possibly caused by other compounds capable of interactions with the AhR (Vorkamp *et al.*, 2012).

Enzyme-linked immunosorbent assays (ELISA) have been successfully applied to PCB analyses in environmental samples, showing reasonable agreement with conventional GC analyses, but with a high dependence on sample pretreatment (Johnson & Van Emon, 1996; Deng *et al.*, 2002). Recent developments include, for example, immunosensors for applications in situ (Lin *et al.*, 2008) and immunoaffinity chromatography for sample purification (Van Emon & Chuang, 2013).

1.2.3 Analysis of environmental samples

Selected methods for analysis of PCBs in environmental matrices are presented in Table 1.12.

Supplementary material on analysis of PCBs in soil and sediment is available online at: http://monographs.iarc.fr/ENG/Monographs/vol107/suppl_S1.pdf.

(a) Air and dust

Both active and passive sampling are used for PCB analysis in air. Passive sampling has been applied to the analysis of outdoor air using semi-permeable membrane devices (Ockenden *et al.*, 2001) and polyurethane foam (Mari *et al.*, 2008). Vegetation is used as a natural passive sampler, for example tree bark integrating atmospheric PCB concentrations over the life time of the tree (Hermanson and Hites, 1990) or pine needles reflecting up to several years of PCB exposure (Kylin *et al.*, 1994).

Polyurethane foam has also been used for indoor air collection (Hazrati & Harrad, 2006), but active sampling is often the preferred method (EPA, 1999; Kohler *et al.*, 2005). To account for concentration differences and the limited air volume in an indoor setting, outdoor air is usually sampled by high-volume sampling, while low-volume sampling is used for indoor air.

Once retained on a solid matrix (filter, sorbent), PCBs are solvent-extracted using the same techniques as commonly applied for soil,

Table 1.12 Selected methods of analysis of PCBs in environmental matrices

Sample matrix	Sample preparation	Assay method	Detection limit[a]	Reference
Air	Collection on sorbent/filter, solvent extraction, evaporation, acid treatment and/or other clean-up (if necessary), separation of dioxin-like and non-dioxin-like PCBs if required.	GC-ECD; GC-HRMS	0.03–10 pg/m^3; 10 pg/m^3	McConnell *et al.* (1998), Mari *et al.* (2008)
Dust	Sieving of samples (during sampling or afterwards), solvent extraction, evaporation, acid treatment, back extraction, clean-up, evaporation.	GC-MS	NA	Harrad *et al.* (2009)
Water	Liquid-liquid extraction or SPE of unfiltered or filtered water, evaporation, clean-up if necessary. Alternative technique: Passive sampling	GC-ECD; GC-HRMS	0.22–3 ng/L; 0.004–0.5 ng/L	Hope *et al.* (1997), EPA (2008a)
Soil	(Water removal), extraction, evaporation, clean-up, including sulfur removal, separation of dioxin-like and non-dioxin-like PCBs if required.	GC-HRMS	1.5 ng/kg; 0.4–46 ng/kg	Wang *et al.* (2010), EPA (2008a)
Sediment	(Water removal), extraction, possibly in combination with sulfur removal, evaporation, clean-up, including sulfur removal, separation of dioxin-like and non-dioxin-like PCBs if required.	GC-ECD; GC-MS; GC-HRMS	NA; 0.4–46 ng/kg	Webster *et al.* (2013), EPA (2008a)

[a] Detection limits are given for individual PCB congeners

PCB, polychlorinated biphenyl; ECD, electron capture detection; EI, electron impact; GC, gas chromatography; HRMS, high-resolution mass spectrometry; MS, mass spectrometry; NA, not available; SPE, solid-phase extraction

sediment or biota. Before extraction, recovery/internal standards are added, e.g. PCB congeners that are not present in the environment, or ^{13}C-labelled PCB congeners. Extraction is often performed by Soxhlet (EPA, 1999; Menichini *et al.*, 2007). Ultrasonic extraction and pressurized liquid extraction (PLE) have also been described (Aydin *et al.*, 2007; Mari *et al.*, 2008). Barro *et al.* (2005) applied headspace-solid phase micro extraction, which does not involve solvents.

Whether or not clean-up steps are required depends on potential interferences from the matrix (e.g. particles) and co-extracted compounds as well as on expected concentrations. Adsorption chromatography can be applied, for example using alumina (Zhang *et al.*, 2011a) or silica. As all PCB congeners are acid stable, acid treatment is possible.

Dust for PCB analysis has been collected in several ways, for example from the residents' vacuum cleaner bags (Franzblau *et al.*, 2009; Knobeloch *et al.*, 2012), by vacuuming (Wilson *et al.*, 2001; Harrad *et al.*, 2009) and from air conditioning units (Tan *et al.*, 2007). Dust samples originating from vacuum bags might be sieved, but cut-off sizes differ, e.g. 150 µm (Wilson *et al.*, 2001) and 1 mm (Knobeloch *et al.*, 2012) have been described.

Extraction techniques are basically the same as described for sorbents, including Soxhlet extraction (Dirtu & Covaci, 2010), PLE (Harrad *et al.*, 2009) and ultrasonic extraction (Wilson *et al.*, 2001). Before extraction, internal/recovery standards should be added, as described for air samples. Due to interferences from the matrix and co-extraction of other compounds, clean-up of dust samples will be required. PLE can be combined with simultaneous clean-up by adding adsorption materials to the cells; however, additional clean-up steps may be necessary (Harrad *et al.*, 2009). Various sorbents have been used for clean-up of dust samples, including Florisil (Wilson *et al.*, 2001; Harrad *et al.*, 2009), silica gel (Dirtu & Covaci, 2010), and combinations of both (Knobeloch *et al.*, 2012). As described for air samples, acid treatment has also been applied (Harrad *et al.*, 2009).

(b) Water

The PCB content in a water sample is strongly influenced by the amount of suspended particulate matter (SPM) that adsorbs PCBs. Depending on the objectives of the analysis, different approaches can be chosen, resulting in different fractions to be analysed:

- Unfiltered water includes dissolved components and those bound to colloids and SPM.
- Filtered water gives PCB concentration on SPM (residue on the filter) and dissolved or bound to colloids (filtrate).
- Passive sampling targets the dissolved fraction.

Passive sampling devices integrate PCB concentrations over time, which reduces temporal variability. Common formats for water sampling include semipermeable membrane devices, low density polyethylene, and silicone rubber (Lohmann *et al.*, 2012). Passive sampling techniques have been applied for analysis of PCBs in river water (Grabic *et al.*, 2010) and seawater (Granmo *et al.*, 2000; Fernandez *et al.*, 2012).

In water bodies with a low SPM content, e.g. seawater, PCB concentrations will likely be low, and large amounts of water will have to be sampled and processed, while avoiding contamination. Guidelines for seawater sampling and the subsequent analysis of organic contaminants have been established by OSPAR (OSPAR, 2013). Studies have shown that the critical part of such analysis occurs outside the laboratory, i.e. during sampling, transport, and storage (Wolska *et al.*, 2005). As described for air and dust, recovery/internal standards should be added before extraction.

PCBs from water samples are typically extracted by either liquid–liquid extraction (LLE), i.e. the direct extraction of PCBs with a non-polar solvent (Hope *et al.*, 1997), or solid-phase extraction (SPE), where PCBs are retained on a solid phase and subsequently eluted with a non-polar solvent (Russo *et al.*, 1999). The United States Environmental Protection Agency (EPA) method 1668B for determination of PCBs in several matrices describes SPE, continuous LLE, and separatory funnel extraction as suitable extraction methods for aqueous samples (EPA, 2008a).

The amount of SPM in the sample is a critical factor, as LLE might be insufficient and SPE cartridges might become blocked by samples with a high SPM content (Erger *et al.*, 2012). Alternatively, SPM might be removed by filtration and analysed separately, for example by Soxhlet or ultrasonic extraction. This could be the method of choice for water samples with a high SPM content, for example wastewater samples or landfall leachate (Zorita & Mathiasson, 2005).

To what extent purification is necessary depends on the nature of the sample, its SPM content, PCB concentration and that of interfering compounds. Although sampling only freely dissolved PCBs, some passive sampling approaches add a clean-up step after extraction, for example using acid silica or aluminium (Grabic *et al.*, 2010). Surface-water samples, however, have often been analysed without clean-up (Hope *et al.*, 1997; Erger *et al.*, 2012), while other studies have included adsorption chromatographic steps (Khim *et al.*, 2001). Gel permeation chromatography (GPC) may be used for water extracts that contain organic compounds of high relative molecular mass (EPA, 2008a).

PCB exposure from snow can be considered insignificant, with the exception of polar regions where snow may be a source of drinking-water. Analytical methods are similar to those for water (Carrera *et al.*, 1998).

1.2.4 Analysis of biological samples

Several matrices have been analysed to determine internal exposure to PCBs, or body burden, including adipose tissue, meconium, placenta, blood, umbilical cord blood, human milk, and hair (Table 1.13).

(a) Tissues (adipose tissue and placenta)

The analytical methods applied to the analysis of PCBs in tissues such as adipose and placenta are similar to those used for environmental samples. The characteristically high lipid content of adipose and other tissues, however, requires rigorous lipid removal before instrumental analysis.

Different ways of sample pretreatment have been applied after or as part of the homogenization procedure, for example sample drying with Na_2SO_4 or hydromatrix (Covaci *et al.*, 2002a; Saito *et al.*, 2004), melting of fat (De Saeger *et al.*, 2005), mixing with base (Kim & Fisher, 2008) and addition of ethanol for protein precipitation (Whitcomb *et al.*, 2005).

Extraction is generally carried out with a non-polar solvent such as toluene or hexane, in some cases in a mixture with acetone, dichloromethane or propanol (Guvenius *et al.*, 2002; Saito *et al.*, 2004; Fernandez *et al.*, 2008). The extraction could often proceed by shaking or rotating, for example in an Ultra Turrex or Vortex (Guvenius *et al.*, 2002). Other extraction techniques are the same as those applied in environmental analyses, including ultrasonic extraction (Suzuki *et al.*, 2005), Soxhlet (Fernandez *et al.*, 2008), PLE (Saito *et al.*, 2004), and MAE (Li *et al.*, 2006). Supercritical fluid extraction with carbon dioxide (sometimes modified with dichloromethane) has also been applied (Stellman *et al.*, 1998). For the extraction of placenta, Gómara *et al.* (2012) additionally described the preparation of a suspension that was liquid–liquid extracted. As for other matrices, recovery/internal standards are generally added before extraction.

Table 1.13 Selected methods for analysis of PCBs in biological matrices

Sample matrix	Sample preparation	Assay method	Detection limit[a]	Reference
Adipose tissue	Pre-treatment (drying and/or protein denaturation), extraction, evaporation, lipid removal, further clean-up, separation of dioxin-like and non-dioxin-like PCBs if required.	GC-ECD; GC-HRMS	0.009–1.1 ng/g lipid; 0.002–0.2 ng/g lipid	Whitcomb *et al.* (2005), Fernandez *et al.* (2008)
Placenta	Pretreatment (drying and/or protein denaturation), extraction, evaporation, lipid removal, further clean-up, separation of dioxin-like and non-dioxin-like PCBs if required.	GC-ECD; GC-MS (ECNI)	NA	Gómara *et al.* (2012), Ma *et al.* (2012)
Blood	Protein denaturation, extraction, evaporation, lipid removal, further clean-up, separation of dioxin-like and non-dioxin-like PCBs if required.	GC-ECD; GC-MS; GC-HRMS	10–100 pg/mL; 2–5 pg/mL	Covaci & Schepens (2001), Lu *et al.* (2012)
Urine (hydroxylated PCBs)	Acidification, extraction, evaporation, derivatization.	GC-MS (EI)	0.02–0.04 ng/mL	Hong *et al.* (2005a, b)
Human milk	Drying or protein denaturation + fat globules dispersion, extraction, evaporation, lipid removal, further clean-up, separation of dioxin-like and non-dioxin-like PCBs if required.	GC-ECD; GC-MS; GC-HRMS	NA; 0.01–0.03 ng/mL; NA	Duarte-Davidson *et al.* (1991), Covaci *et al.* (2001), Fürst (2006)
Hair	Washing, incubation with HCl, extraction, evaporation, lipid removal, further clean-up.	GC-ECD; GC-MS (EI)	0.3–2 ng/g	Covaci *et al.* (2002b)

[a] Detection limits are given for individual PCB congeners

ECD, electron capture detection; ECNI, electron capture negative ionization; EI, electron impact; GC, gas chromatography; HCl, hydrochloric acid; HRMS, high-resolution mass spectrometry; MS, mass spectrometry; NA, not available

A common method for lipid removal is treatment of the sample with acid, usually sulfuric acid (Whitcomb *et al.*, 2005). GPC is another suitable method (Ma *et al.*, 2012), but may not achieve complete removal of lipids. The use of partially deactivated neutral aluminium for lipid removal has also been described (Stellman *et al.*, 1998).

For further clean-up of the extracts, the same techniques are applied as in the environmental analyses, either individually or in combinations. These include silica gel (Suzuki *et al.*, 2005; Fernandez *et al.*, 2008), alumina (Covaci *et al.*, 2002a), Florisil (Whitcomb *et al.*, 2005) and GPC (Saito *et al.*, 2004). Impregnating the silica gel with acid is a common way of combining adsorption chromatography with lipid removal (Covaci *et al.*, 2002a; Fernandez *et al.*, 2008).

Some studies have analysed PCB metabolites in adipose tissue and placenta, e.g. hydroxylated PCBs and methylsulfonyl-PCBs. These methods usually included a fractionation by adsorption chromatography and elution with different solvents (Guvenius *et al.*, 2002; Saito *et al.*, 2004). In the method by Gómara *et al.* (2012), hydroxylated PCBs were separated from the parent compounds during liquid-liquid extraction (LLE). After derivatization, the fraction containing hydroxylated PCBs was cleaned up in the same way as described for the parent compounds.

(b) Blood (including umbilical cord blood)

Numerous studies have analysed PCBs in blood, mostly in serum, but also in plasma (Schettgen *et al.*, 2011). The analytical methods used generally do not differ for serum and plasma. Given the low lipid content of blood, PCB concentrations are generally low and the sample amount available for analysis may be a challenge. Most studies work with volumes of 0.5–2 mL. Methods have recently been developed to extract PCBs from only 50 µL of plasma and from dried blood spots (Lu *et al.*, 2012).

Umbilical cord blood has often been analysed in combination with maternal blood, using the same methods. Given the lower lipid content and usually lower PCB concentrations in cord blood, adjustments of the sample intake might be useful; however, sample availability is usually the limiting factor.

Apart from the addition of internal standards, the first step in PCB analysis of serum, plasma or cord blood is generally the denaturation of protein, e.g. by addition of formic acid (Kang *et al.*, 2008), methanol (Korrick *et al.*, 2000), or acetonitrile (Agudo *et al.*, 2009). Different extraction techniques have been described, among which the simple mixing of the sample with solvent (Apostoli *et al.*, 2005; Schettgen *et al.*, 2011). LLE has also been used (Kawashiro *et al.*, 2008; Bachelet *et al.*, 2011) as well as SPE on C_{18} or hydrophilic–lipophilic balanced reversed phase sorbent (Covaci & Schepens, 2001; Lee *et al.*, 2011). Guvenius *et al.* (2003) used Lipidex 5000, a lipophilic gel, for extraction of PCBs from cord blood.

Since they are present at low concentration, lipids are not always removed from the extract (Lu *et al.*, 2012). Lipids can be removed by direct addition of acid to the extracts (Atuma & Aune, 1999) or by clean-up methods on acidified silica (Covaci & Schepens, 2001). Further clean-up sorbents include Florisil (Whitcomb *et al.*, 2005), alumina (Stellman *et al.*, 1998), neutral silica gel (Atuma & Aune, 1999), or combinations of these (Guvenius *et al.*, 2003; Apostoli *et al.*, 2005).

To account for the low concentrations of PCBs in blood, extracts are often reduced to very small volumes, e.g. 50 µL (Covaci & Schepens, 2001). This is achieved by addition of non-volatile keepers (Covaci & Schepens, 2001), or by evaporation to dryness (Apostoli *et al.*, 2005) and reconstitution in the desired solvent or a solution of syringe standards in this solvent. Evaporation to dryness carries the risk of loss of volatile PCB congeners.

Hydroxylated PCB metabolites have been analysed in blood and umbilical cord blood. Guvenius *et al.* (2003) used the same extraction method as for parent PCBs, but obtained hydroxylated PCBs in an isolated fraction, based on different elution solvents. Park *et al.* (2009) treated the sample with hydrochloric acid and 2-propanol, and extracted hydroxylated PCBs by LLE. Hydroxylated PCBs require derivatization to non-polar molecules before separation by GC (Sandau *et al.*, 2000).

(c) Urine

A few studies have assessed PCB metabolites (hydroxylated PCBs) in urine samples. Hydroxylated PCBs are more polar than their parent compounds and act as weak acids, which has to be taken into account in extraction, clean-up, and separation by GC.

Hong *et al.* (2005a, b) presented two methods for the extraction of hydroxylated PCBs from urine. The first method combined SPE testing of four different phases, with five derivatization methods. Best recoveries and GC separations were found for hydroxylated PCBs extracted on a C_2 phase and derivatized with iodopropane under basic conditions (Hong *et al.*, 2005a). The second method used headspace solid-phase microextraction and on-fibre derivatization, achieved by placing the needle in the headspace of a solution of bis(trimethylsilyl)trifluoroacetamide (BSTFA) (Hong *et al.*, 2005b). The derivatized hydroxylated PCBs were transferred to the GC injector by thermic desorption. Several fibre materials were tested, of which polydimethylsiloxane-divinylbenzene (PDMS-DVB) gave the highest signal in the analysis.

(d) Human milk

Breast milk is the most extensively analysed matrix for the estimation of PCB body burden in humans. The first studies date back to the 1970s (Musial *et al.*, 1974), and programmes for the biomonitoring of human milk have been established in several countries or regions (Wilhelm *et al.*, 2007; Krauthacker *et al.*, 2009; Cerná *et al.*, 2012). Analytical methods are very diverse: the milk samples may be treated as liquid, or the lipid phase may be isolated, or the sample may be freeze-dried and treated as solid.

When the whole milk sample is treated as a liquid, the first steps usually include protein denaturation and dispersion of fat globules by addition of sodium oxalate, or acetic acid and methanol, sometimes in combination with ultrasound treatment (Dmitrovic & Chan, 2002; Fürst, 2006). Before or after this step, internal standards are usually added, and the sample is extracted by LLE (Chovancová *et al.*, 2011), or SPE (Covaci *et al.*, 2001; Dmitrovic & Chan, 2002). Hexane is a commonly used solvent, although a large variety of solvent combinations and solvent sequences have been described in the literature.

In some studies, the lipid phase of the milk sample is separated or extracted and a defined amount of fat used for further analysis (Fürst, 2006; Pérez *et al.*, 2012).

In the third approach, milk samples are freeze-dried and a defined amount is extracted with techniques commonly applied to solid samples, e.g. Soxhlet extraction (Duarte-Davidson *et al.*, 1991) and PLE (She *et al.*, 2007). Matrix solid-phase dispersion has also been described (Gómara *et al.*, 2011). However, freeze-drying always runs the risk of loss of volatile PCBs and cross-contamination.

As described for other human matrices, lipids in the extract are removed before instrumental analysis. Furthermore, the extracts usually contain co-extracted compounds that are likely to interfere with PCBs in the instrumental analysis. The clean-up techniques therefore generally include lipid destruction by acid treatment, either directly in the extract (Duarte-Davidson *et al.*, 1991), or by acidified silica gel (Covaci *et al.*, 2001). Alternatively, GPC has been used, but usually in combination with acid treatment (She *et al.*, 2007). Further clean-up techniques include

adsorption chromatography on neutral or basic silica (She *et al.*, 2007), alumina (Chovancová *et al.*, 2011), and Florisil (Pérez *et al.*, 2012), also in combinations (Fürst, 2006). Ingelido *et al.* (2007) described clean-up by supercritical fluid extraction.

(e) Human hair

With a lipid content of about 2% (Altshul *et al.*, 2004), hair accumulates lipophilic compounds such as PCBs and has the advantage of being sampled non-invasively. However, to what extent hair PCB content reflects internal exposure to PCBs is difficult to determine, even if the hair is washed before analysis to avoid co-extraction of dust particles. Comparisons of serum and hair samples showed weak correlations for most PCB congeners and considerably higher PCB concentrations in hair, also on a lipid-normalized basis (Altshul *et al.*, 2004). Effects of hair colour (natural or dyed) cannot be ruled out (Covaci *et al.*, 2002b).

Sample amounts of less than 1 g are sufficient for detection of PCBs. The hair samples are washed, and cut or pulverized, and then spiked with internal or recovery standards and incubated with hydrochloric acid (Covaci *et al.*, 2002b). Extraction techniques applied in hair analyses include LLE (Covaci *et al.*, 2002b), Soxhlet (Zhang *et al.*, 2007), and ultrasonic extraction (Barbounis *et al.*, 2012). The same methods for lipid removal and extraction clean-up as for other biological matrices have been used, e.g. adsorption chromatography on acidified silica gel, alumina (Covaci *et al.*, 2002b), and Florisil (Zhang *et al.*, 2007). A comparison between three laboratories analysing the same hair sample but using different internal standards, extraction techniques and analytical instruments (GC-ECD, GC-LRMS and GC-HRMS) showed good agreement, with a relative standard deviation of 15% (Gill *et al.*, 2004).

1.2.5 Analysis of food samples

Food items are regularly analysed for PCBs in various national and international food-monitoring programmes (Fromberg *et al.*, 2011; EFSA, 2005), and market-basket or duplicate-diet studies have been performed to identify PCB intake from food (Voorspoels *et al.*, 2008; Fromme *et al.*, 2009).

These studies have often applied methods that are sufficiently versatile to allow analysis of different kinds of food item with varying lipid content and consistency. The first step is often a drying of the food material with sodium sulfate (Voorspoels *et al.*, 2008; Schecter *et al.*, 2010), followed by the addition of recovery or internal standards, and Soxhlet extraction using hexane:acetone (Voorspoels *et al.*, 2008), or toluene (Kiviranta *et al.*, 2004). The clean-up usually includes lipid removal by acid treatment, either as direct addition to the extracts (Fromme *et al.*, 2009), or via acid-impregnated silica gel (Voorspoels *et al.*, 2008). Further clean-up steps can include neutral and basic silica gel (Son *et al.*, 2012), alumina (Kiviranta *et al.*, 2004), and Florisil (Schecter *et al.*, 2010); however, the extent of purification and fractionation is highly dependent on the target analytes.

Food monitoring sometimes focuses on DL-PCBs, which are analysed together with dioxins and furans. These are separated from other PCB congeners by fractionation on a carbon column, which separates the molecules by planarity (Fernandes *et al.*, 2004). Given the low concentrations of DL-PCBs, the fractions are sometimes further purified before instrumental analysis (Fromme *et al.*, 2009).

Some studies have used more specific methods for different food items, for example, protein denaturation and dispersion of fat globules in dairy products, by the addition of sodium oxalate, or potassium oxalate and ethanol (Fromberg *et al.*, 2011; Sirot *et al.*, 2012), followed by LLE. In other studies using cows' milk, the samples

are freeze-dried before extraction (Lake *et al.*, 2013), or the fat is separated using a detergent (Pérez *et al.*, 2012). The clean-up steps may be the same as for other lipid-containing matrices. For the analysis of butter and vegetable oil, Roszko *et al.* (2012) described a dialysis method based on low-density polyethylene semi-permeable membranes, followed by GPC and common column clean-up.

Numerous studies have dealt with analysis of PCBs in fish, as summarized by Domingo & Bocio (2007). Analyses of meat and fish basically follow the same methods (Su *et al.*, 2012). Samples are often dried as the first step, e.g. by freeze-drying (Abalos *et al.*, 2010; Liu *et al.*, 2011) or addition of anhydrous sodium sulfate (de Boer *et al.*, 2010). After addition of internal standards, the samples are extracted on a Soxhlet apparatus (Su *et al.*, 2012), by PLE (Pérez-Fuentetaja *et al.*, 2010), or ultrasonic extraction (Son *et al.*, 2012). The clean-up techniques are the same as described for other food matrices, including acid treatment (Su *et al.*, 2012), acid and neutral silica gel, and alumina (Liu *et al.*, 2011), and Florisil (Villa *et al.*, 2011), sometimes in an automated PowerPrep system (Abalos *et al.*, 2010). A rapid extraction and purification method was presented by Kalachova *et al.* (2011), combining PCB partitioning into ethyl acetate and lipid removal on a silica gel microcolumn.

Eggs are commonly analysed for PCBs, with a focus on the egg yolk (Kiviranta *et al.*, 2004; Voorspoels *et al.*, 2008). While the same methods could be applied as for other food samples, recent publications have only equilibrated the sample with solvents (Fromberg *et al.*, 2011; Rawn *et al.*, 2012). The clean-up steps include lipid removal by direct acid treatment and adsorption chromatography on acid silica and Florisil (Rawn *et al.*, 2012).

Fruit and vegetables are analysed less frequently than lipid-rich food items. In the methods described by Grassi *et al.* (2010) and Sirot *et al.* (2012), freeze-drying, extraction using Soxhlet or PLE, and acid treatment were applied, in a manner very similar to that used for analyses of other food items.

1.3 Production and uses

1.3.1 Production processes

PCBs have commonly been synthesized commercially by catalytic chlorination of biphenyl. The catalysts used include iron, iodine, and chlorides of aluminium, tin, and antimony. The synthesis is performed as a one-step chlorination process, or in two steps with further chlorination of residues from the first step. The crude products are purified by alkali wash to remove hydrogen chloride and ferric chloride, blown with air, and sometimes also by distillation (IARC, 1978). The degree of chlorination is controlled by the time (range, 12–36 hours) in the reactor.

The manufacturing process for Aroclors involved the chlorination of biphenyl with anhydrous chlorine in the presence of a catalyst, such as iron filings or ferric chloride. In 1974–1977, "late production" Aroclor 1254 was made by a two-stage chlorination procedure. In the first stage, biphenyl was chlorinated to 42% chlorine content by weight as for Aroclor 1242. This was then fractionated to give a distillate (Aroclor 1016). The residue (mostly mono-*ortho* tetrachlorobiphenyls and higher homologues) was further chlorinated to 54% chlorine by weight, resulting in a lot (Monsanto lot KI-02–6024) with markedly higher levels of the high non-*ortho* and mono-*ortho* PCB congeners than the Aroclor 1254 lots produced earlier. The differences between the early and late lots of Aroclor 1254 are discussed in more detail above (see Section 1.1.3 and Table 1.10).

1.3.2 Production volumes and trends

Although the commercial production of PCBs began in the 1920s, it was not until after 1945 that production reached substantial volumes. Production peaked in the 1960s and 1970s, and had ceased in most countries by the end of the 1970s or early 1980s.

Estimates of the total cumulative worldwide production of PCBs indicate that 1 to 1.5 million tonnes (or more) of commercial PCB products were manufactured. Production volumes from former Czechoslovakia, France, Germany, Italy, Japan, China, Poland, the Russian Federation and the former Soviet Union, Spain, the United Kingdom, and the USA, as reported by Tatsukawa (1976), de Voogt & Brinkman (1989), Jiang *et al.* (1997), AMAP (2000), Holoubek *et al.* (2001a), and Sułkowski *et al.* (2003), add up to around 1 325 000 tonnes for 1930–1993 (Table 1.14).

In the USA, annual production peaked in 1970 with a total volume of 39 000 tonnes. From 1957 to 1971, 12 different types of Aroclor with chlorine contents ranging from 21% to 68% were produced in the USA by Monsanto Chemicals Co. (see Section 1.1). In addition, Geneva Industries produced a smaller amount of PCBs from 1972 to 1974 (EPA, 2008b).

In China, the production of PCBs began in 1965 and was gradually stopped between 1974 and the 1980s. According to preliminary investigation and analysis, 7000–10 000 tonnes of PCBs were produced in China from 1965 to 1974, with 9000 tonnes as PCB_3 [similar to Aroclor 1242] and 1000 tonnes as PCB_5 [similar to Aroclor 1254] (Xing *et al.*, 2005; NIP China, 2007).

Information from the Democratic People's Republic of Korea (NIP Korea DPR, 2008) indicated that production of PCBs has been ongoing at two sites since the 1960s. The initial production capacity for PCBs was 1200 tonnes per year, with a tendency to increase until the 1980s; however, capacity has decreased since the early 1990s, and the average annual production volume in 2001–2006 was 411.6 tonnes. The total amount produced up to 2006 could be estimated at around 30 000 tonnes. According to this report, the Democratic People's Republic of Korea planned to reconsider its production of PCBs in 2012.

The commercial products were marketed under more than one hundred different trade names, depending on place of manufacture, production process, and chlorine content. Aroclors comprised at least 10 different commercial PCB products, under the names Aroclor 1016, 1221, 1232, 1242, 1248, 1254, 1260, 1262, 1268, and 1270. It should be noted that Aroclor 5460 was not a PCB product, but consisted of polychlorinated terphenyls. Other commercial PCB products include Clophen (four products), Delor (three products), Fenclor (five products), Kanechlor (five products), Phenochlor (four products), Pyralene (three products), Sovol, and Therminol (see Section 1.1.3).

1.3.3 Uses

Due to the physical and chemical properties of PCBs, such as non-flammability, chemical stability, high boiling point, and high dielectric constants, PCBs were widely used in several industrial and commercial open and closed applications (Table 1.15). PCBs have also been used in corresponding military applications, but detailed information on military use is typically very scarce.

As a result of the production process, PCBs were never used as individual congeners, but as technical products composed of multiple congeners. The commercial PCB products were generally used as such, but mixtures with other compounds were also produced to obtain specific properties. For example, the PCB product Sovol may have been mixed with α-nitronaphtalene to increase volatility, and sold as Nitrosovol (UNEP, 1988). Similarly, Galbestos was a mixture of PCBs and asbestos used on galvanized steel and

galvanized corrugated sliding panels in various industrial and military applications.

(a) Closed applications

The predominant applications for PCBs were in dielectric fluids in capacitors and transformers. These applications are considered to be closed applications, since PCBs are not expected to leak out of the system. However, transformers had occasionally to be topped up with PCBs so that these systems were not completely closed.

While applications in hydraulic and heat transfer, and cooling systems are also usually considered to be closed applications, there have been reports of accidental leaks from such systems, and thus these applications are often referred to as "normally closed."

During the 1960s, dielectric fluid in capacitors and transformers represented 50–60% of the sales of PCBs in the USA (IARC, 1978). In 1972, Monsanto restricted its sale of PCBs to capacitor and transformer applications (Erickson, 2001); after this date, these applications represented some 99% of the total use of PCBs in the USA (Durfee *et al.*, 1976). In China, PCB_3 [similar to Aroclor 1242] was used primarily in power capacitors applied in electricity production, distribution and transmission, while PCB_5 [similar to Aroclor 1254] was used mainly as a paint additive (see Table 1.8).

As production and use of PCBs became banned, outdated PCB-containing equipment (equipment filled with PCBs as dielectric fluid) was generally removed from use and stored for disposal (Xing *et al.* 2005). In this equipment, about 6000 tonnes of PCBs came from capacitors (NIP China, 2007).

(b) Open applications

PCBs were also used in several open applications as a major constituent of permanent elastic sealants and as flame-retardant coatings (Heinzow *et al.*, 2007).

The use as plasticizer in sealants (caulking material) and flooring material was common in many countries, representing up to 15–20% of the total use of PCBs in Sweden (Jansson *et al.* 1997). The sealants were mainly used in outdoor applications, but indoor use was not uncommon. Use in flooring material was limited to indoor use.

Sealants that were mixed with PCBs were mainly of the polysulfide type. The mixing was often performed on site. Information on concentrations to be used were not available to the Working Group; however, from a technical point of view, PCB concentrations were likely to be above 5%. Sealants analysed some 40 years after application often contained concentrations of PCBs of 5–15%, with concentrations of up to 35% being reported. The concentration may vary not only between sites, but also within a building. These variations may be the result of use of sealants with different PCB content, or of secondary processes, such as migration out of the matrix. There are reports indicating that inner parts of sealants could contain higher concentrations than the superficial parts (Johansson *et al.*, 2003).

In addition to the use as sealants and flame-retardant coatings, PCBs have also been used in other open applications, such as in inks, adhesives, microencapsulation of dyes for carbonless duplicating paper, conveyor belts, rubber products, paints, pesticide fillers, plasticizers, polyolefin catalyst carriers, immersion oil for microscopes, cutting and lubricating oils, surface coatings, wire insulators, and metal coatings (ATSDR, 2000; Erickson, 2001; Erickson & Kaley, 2011). Also, use in small ballasts for fluorescent lights could be regarded as an open application, especially after long-lasting usage.

(c) Disposal of equipment containing PCBs

Improper handling of electronic waste (e-waste) has been identified as a source of environmental contamination with PCBs, especially for old equipment (Leung *et al.*, 2006). Dismantling of ships has also been identified as a potentially important source of occupational exposure to and environmental contamination with PCBs (Basel Convention, 2003).

With the complete ban on the use of PCBs, stockpiles awaiting elimination have successively appeared in many countries.

In 2000, 23 companies worldwide had facilities for the disposal of equipment containing PCBs, of which 11 were in Europe. The use of solvent for decontamination represents the most common procedure of disposal, followed by destruction by incineration, dechlorination with sodium, retrofilling and vitrification. The most common technology used for destruction of PCBs is by incineration, with an efficiency of between 99% and 99.99999% (IOMC, 1998). For exemple, France has an installed capacity for incineration of PCB residues amounting to around 20 000 tonnes per year (INERIS, 2013).

1.4 Environmental occurrence and exposure

PCBs are found worldwide at measurable levels in all environmental media (soils and sediments, water, air), in wildlife, and also probably in the body of every human. Human exposure to PCBs occurs mostly via ingestion of

contaminated food (see Section 1.4.7), but also via inhalation and dermal absorption.

Soils are natural sinks for persistent and lipophilic compounds such as PCBs; PCBs are absorbed by the organic carbon of the soil, and once absorbed they are relatively persistent (Buckley-Golder, 1999) (see Section 1.4.5). PCBs enter the soil via different pathways: industrial releases from manufacture, use and disposal, accidental releases, atmospheric deposition, application of sewage sludge, and erosion and leachate from nearby contaminated areas. PCBs in organic liquids may be dissolved by soils and then migrate with the solvent.

The congener patterns of PCBs in soils and sediments change over time as a result of the activity of aerobic bacteria (that degrade less chlorinated congeners) and anaerobic bacteria (that can cause partial dechlorination of more highly chlorinated congeners) (Hardell *et al.*, 2010). The patterns found in environmental biota are often referred to as "weathered," since they result from alterations in the composition of a mixture (e.g. resulting from bio accumulative and metabolic processes in higher biological organisms and through bacterial action, exposure to ultraviolet radiation, etc.). "Weathering" processes result in PCB patterns with either a higher chlorinated fraction or congeners with higher bioaccumulative properties compared with the commercial products. "Weathering" must be considered when assessing PCB-associated risks based on studies with experimental animals exposed to commercial PCB products.

Water is a major pathway for migration of PCBs, both in solution and particulate-bound, although PCBs are lipophilic and generally not very soluble in water (see Section 1.4.6). Less chlorinated PCB congeners have greater solubility than more highly chlorinated congeners.

Air is another major pathway for PCB migration (see Sections 1.4.3 and 1.4.4). PCBs are semi-volatile compounds and, as with water solubility, less chlorinated congeners are more volatile than more highly chlorinated ones (Totten *et al.*, 2006). There is extensive evidence that PCBs in aquatic systems exchange with PCBs in air (Bamford *et al.*, 2002). Air transport of PCBs can occur in either the vapour phase or particulate-bound, thus contributing to global pollution and PCB contamination of remote regions of the earth. PCBs in air come from several direct or indirect sources, including industrial facilities, military sites, contaminated bodies of water, landfills and hazardous waste sites, electric arc furnaces, incineration and other forms of combustion, sewage sludge applied to agricultural lands, and construction materials, including in paints (Hu & Hornbuckle, 2010), caulking, light ballasts, floor sealants, and adhesives and plasticizers in older buildings (Wallace *et al.*, 1996).

PCBs from soil, sediment, air and water enter the food-chain by uptake and bioaccumulation in plants and animal fats. There is significant biological magnification of PCB concentration as PCBs move up the food-chain. PCB concentrations vary depending on the degree of bioaccumulation, and are usually highest in carnivorous fish coming from contaminated waters. PCBs are found in the fat of all meat animals, in all dairy products containing fat, and in eggs (ATSDR, 2000; IOM, 2003), sometimes at high concentrations due to local contamination of grasses, and feeding practices in some countries (see Section 1.4.2). Also, it is not uncommon to feed domestic animals with fish meal or oil, or waste animal fats, which results in recycling of PCBs (IOM, 2003). For example, farmed salmon fed with concentrated fish meal or fish oil containing significant amounts of PCBs showed elevated concentrations of PCBs (Hites *et al.*, 2004). PCBs found in food are typically of higher chlorination, since they are less volatile and more biologically persistent in plants and animals than the lower congeners.

Another important route of exposure to PCBs is inhalation; however, it is difficult to determine the relative contribution of inhalation

compared with ingestion. Harrad *et al.* (2006) have suggested that inhalation may account for 4–63% (median, 15%) of overall exposure in humans. PCBs may be attached to indoor dust, which can be either ingested or inhaled. Individuals who spend significant periods of time in the presence of either outdoor or indoor vapour-phase PCBs will have continuous exposure that is not reflected in measurements of "total" PCBs, because the less chlorinated congeners are more rapidly metabolized and excreted by the human body (Fig. 1.5; Johansson *et al.*, 2003). Concentrations of different PCB congeners were measured in blood from individuals living in houses where PCB-containing sealant was used. Concentrations of most congeners were only slightly elevated (1.2 to 3.2 times), but the two congeners with a low level of chlorination (PCB-28 and PCB-66) were detected at much higher concentrations (30 and 9 times, respectively) in contaminated flats than in control flats.

Dermal absorption of PCBs may occur primarily in the occupational setting, but also through contact with contaminated sediments or other applications to the skin (Wester *et al.*, 1987, 1993). Less chlorinated congeners are more rapidly absorbed through the skin than more highly chlorinated congeners (Garner & Matthews, 1998).

Congener patterns in the general human population are always different from any pattern found in commercial PCB products (Patterson *et al.*, 2009). The factors that may explain this are:

- The general public is exposed to multiple sources of PCBs, only rarely to a single commercial product.
- There may be more than one route of exposure for almost all matrices/animals/humans.
- Dechlorination occurs to varying degrees in sediments, soils, water and air. Commercial PCB products will volatize to some degree, and in doing so, will lose less chlorinated congeners.
- PCBs ingested by fish and animals will be metabolized (to less chlorinated and hydroxylated congeners) to different degrees. Thus most food stuffs will demonstrate a shift in the congener profile compared to the commercial product.
- When inhalation is the major route of exposure, there is selective exposure to the more volatile, less chlorinated and less persistent congeners.
- Genetic differences among individuals may confer differences in metabolic activity and selective metabolism of different congeners.

1.4.1 Diffuse sources of PCBs worldwide

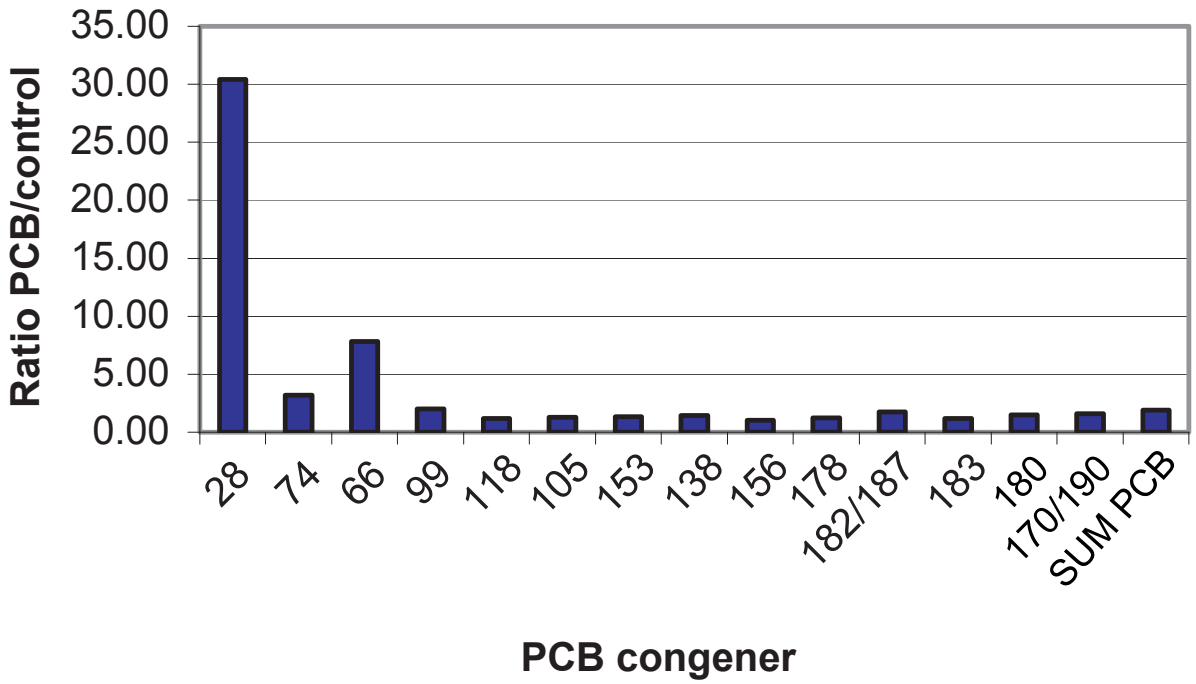
(a) North America

The two Monsanto facilities that manufactured PCBs in the USA were located in Anniston, Alabama, and Sauget, Illinois. In Anniston, more than 400 000 tonnes of PCBs were produced, at least 4550 tonnes were discarded in two landfills, and at least 20.5 tonnes were released into the atmosphere (Hermanson & Johnson, 2007). Many of the large industries using PCBs manufactured by Monsanto were located near major bodies of water, and PCBs were released into the environment as a result of unintentional leaks, volatilization during the production process, and migration from associated landfills and waste products. There was also production, at lower quantities, by Geneva Industries in Houston, Texas (de Voogt & Brinkman, 1989). As a result, contamination has occurred in many rivers and streams near these sites of production (see Section 1.4.6(a)).

(b) Europe

In western Europe, many chemical plants are located along major rivers (i.e. Rhine, Rhone, and Seine) and there have been several isolated incidents of organic chemical pollution. The Seine estuary remains one of the most polluted

Fig. 1.5 Blood PCB concentrations in individuals living in PCB-contaminated flats relative to individuals living in control flats



PCB, polychlorinated biphenyl
From Johansson et al. (2003)

in Europe (RNO, 2012). Also, the Venice lagoon in Italy is particularly polluted owing to the proximity of an important industrial district (the Marghera Harbour) (see Section 1.4.6(b)).

In the Slovak Republic, the Chemko Chemical Co. (based in the Michalovce district) produced 21 000 tonnes of commercial PCB mixtures between 1959 and 1984 (Delor 103, 104, 105, 106, Delotherm DK and DH, Hydelor 137). Improper disposal from the Chemko plant via release of effluent directly into the Laborec river resulted in long-term environmental contamination.

During the conflict of the former state union of Serbia and Montenegro throughout the 1990s, the burning or damaging of industrial and military targets resulted in the release of large amounts of PCBs into the environment: more than 1000 electro-transformer stations that contained PCB oil were damaged. After the bombardment of Kragujevac, Serbia, 2500 kg of PCB-based oil from the transformers of the Zastava automobile industry were spilled.

A French inventory reported that the number of installed transformers containing at least 100 kg of PCBs was 100 000 units in 1987, corresponding to 50 000 tonnes of fluids containing 60% PCBs (Pyralene), and to 50 000 tonnes of carcasses with 5% of PCB residues. The 250 000 medium-voltage capacitors represented about 3000–5000 tonnes of pure PCBs, while the low-voltage capacitors represented 1500–2000 tonnes of hardly extractable PCBs.

In Spain, an inventory in 1997 reported some 6000 tonnes of PCBs, although the amount of material containing or contaminated with PCBs could reach 200 000 tonnes.

(c) Asia

Contamination of soil and sediments has been reported in the Russian Federation, China, Viet Nam, and Japan. Such contamination may originate from PCB producing plants (e.g. China, Japan, Democratic People's Republic of Korea), or from e-waste recycling facilities (e.g. China). In addition, two major accidents of food contamination occurred in Taiwan, China and Japan (see Section 1.4.2(a)).

(d) South and Central America

There has been no manufacture of PCBs in South and Central America, but there has been widespread use of PCB-containing transformers and other PCB-containing devices.

(e) Africa

There has been no manufacture of PCBs in Africa, but there has been widespread use of PCB-containing transformers and other PCB-containing devices. In Africa, several studies showed an increase in the number of sources of PCBs, due to leakage and wrongly disposed transformers, shipwrecks, and biomass burning.

Another major source of exposure is the importing of e-waste and increase of e-waste recycling facilities, usually illegal, but common in Ghana, Senegal, Nigeria, Kenya, and the United Republic of Tanzania. A report by the United Nations Environment Programme (UNEP) documented issues concerning e-waste in South Africa, Kenya, Uganda, Morocco, and Senegal (UNEP, 2009).

In spite of the lack of homogenous data, an attempt has been made to compare the main PCB stocks that reside in the various countries of the region. [These data should only be seen on the relative scale since lacking the accuracy to make them valuable in the absolute sense.]

In Algeria, the national inventory of electrical equipment and PCB wastes identified 6770 appliances and around 4000 tonnes of oil to remove. The deposit of transformers, capacitors and various equipment containing PCBs was estimated at 1700 tonnes in Tunisia and 1150 tonnes in Morocco (Business Med, 2010).

1.4.2 Accidental releases into the food-chain

(a) Asia

Cooking oil contaminated by Kanechlor has been the source of two accidental mass poisonings in western Japan (later called "Yusho," oil disease in Japanese) and in Taiwan, China (later called "Yucheng," oil disease in Chinese). Commercial PCB mixtures were used as heat-transfer media in oil tanks; leakage of the pipes caused exposure to the PCB mixture and PCB pyrolytic products, mainly PCDFs and polychlorinated quaterphenyls (PCQs) (Masuda *et al.*, 1986). Patients from both countries have been exposed to comparable quantities of PCBs and PCDFs. The PCB/PCDF concentrations in the Yusho oil were higher (several hundred ppm to 3000 ppm) than those in the Yucheng oil (53 to 100 ppm) (Guo *et al.*, 2003); however, on average, Yucheng patients consumed the contaminated oil for a longer duration than the Yusho patients.

(i) Yusho incident, Japan

In 1968, the Yusho incident involved approximately 1800 people who ingested rice oil contaminated by Kanechlor 400 and its pyrolytic products, mainly in Fukuoka and Nagasaki prefectures (Masuda, 1994a, b; Kuratsune, 1996; Matsueda *et al.*, 1993; Todaka *et al.*, 2007a; Nagayama *et al.*, 1977; Tanabe *et al.*, 1989; Masuda *et al.*, 1998; Ohta *et al.*, 2008a). Affected people developed a "strange skin disease," including acne-form eruption, follicular accentuation, and pigmentation, as well as eye discharge and swelling of eyelids. The mean concentrations of seven PCB congeners (PCB-105, PCB-118, PCB-138, PCB-153, PCB-157, PCB-170, and PCB-180) detected in blood were 6.7 ppb and 3.84 ppb (95% confidence

interval, 3.54–4.17), 5 and 20 years after being exposed, respectively (Masuda & Yoshimura, 1982). Mortality data among registered Yusho patients were identified by follow-up studies to 1990 and 2007. The first of these two reports (Ikeda & Yoshimura, 1996) reported serum PCB concentrations in the range of 0 to 35 ppb in 1972, and a decrease to about 5 ppb in 1984 (Iida *et al.*, 1999) (see Sections 1.4.9(b)(iii) and (c)(iv) for additional data on PCB concentrations in blood and adipose tissue, respectively).

(ii) Yucheng incident, Taiwan, China

In 1978–9, the Yucheng incident involved approximately 2000 people who ingested rice oil contaminated with Kanechlor 500 and its pyrolytic products (Hsu *et al.*, 1985). After a few months, these people developed chloracne, hyperpigmentation, severe fatigue, peripheral neuropathy, and other signs and symptoms similar to Yusho disease. On the basis of a dietary questionnaire, it was estimated that Yucheng patients had consumed on average about 1 g (range, 0.7–1.4) of PCBs and 3.8 mg (range, 1.8–5.6) of PCDFs (Lan *et al.*, 1981). Another study estimated the intakes of PCBs, PCDFs, and PCQs by Yucheng patients at 673, 3.8, and 490 mg, respectively (Masuda *et al.*, 1986). DL-PCBs contributed to approximately 30% and 20% of the total TEQ (toxic equivalent) in Yucheng men and women, respectively. Compared with the general population in Taiwan, China, the mean total serum PCB concentrations in the Yucheng victims were still nine times higher 15 years after exposure (see Sections 1.4.9(b)(iii) and (c)(iv) for additional data on PCB concentrations in blood and adipose tissue, respectively).

(b) Europe

In Europe, the "Belgian dioxin crisis" was caused by the accidental release of 50 kg of a commercial PCB mixture contaminated with 1 g of dioxins commonly found in transformers, to a stock of recycled fat used for the production of 500 tonnes of animal feed. In May 1999, it appeared that more than 2500 poultry and pig farms could have been contaminated. Chickens showed the classical signs of oedema disease.

In Ireland in 2008, a tank for storage of pork fat was contaminated with heat-transfer fluid containing PCBs (Hovander *et al.*, 2006). [The Working Group noted that the label of "dioxin crisis" attributed to these episodes of PCB feed contamination was inappropriate.]

1.4.3 Outdoor air

PCBs in outdoor air may be a significant source of exposure. Concentrations of PCBs in air depend on a variety of factors, including temperature and proximity to local sources. Temperature is particularly important in controlling the cycle of volatilization and precipitation. Proximity to local sources, such as industrial facilities, landfills, or contaminated bodies of water, results in elevated air concentrations of both vapour phase and particulate-bound PCBs that dissipate with distance at different rates, resulting in both local and distant contamination. Combustion and other high-temperature processes generate PCBs, in particular during combustion of highly chlorinated compounds; however, this route of unintentional formation is considered to contribute little to total airborne PCBs. Migration to the outdoor environment has also been shown to occur as a result of erosion of exposed sealants.

(a) North America

PCB concentrations in outdoor air vary greatly between urban and rural sites in North America, and may be very high near industrial facilities and other contaminated sites (Table 1.16). These differences reflect primarily the impact of local sources and dilution in air, but also the deposition of PCBs at lower temperatures.

The major sources in Chicago are from landfills, sewage sludge drying beds, and transformer storage yards (Hsu *et al.*, 2003). Shen *et al.*

Table 1.16 PCB concentrations in outdoor air in North America

Reference	Location, sources	PCBs measured	PCB concentration in pg/m³ as mean and/or range	Comments
Vorhees *et al.* (1997)	Near a PCB-contaminated site, New Bedford Harbor, Massachusetts	"PCB concentrations"	400–61 000	
	Comparison neighbourhood		100–8200	
Hung *et al.* (2001)	Canadian Arctic	Sum of 102 congeners	28 in 1993; 23 in 1997	PCB-28, PCB-52, and PCB-118 showed little or no decline over time
Hermanson *et al.* (2003)	Near the former Monsanto PCB-manufacturing facility in Anniston, Alabama	Sum of 120 congeners	8700–82 000 [annual average, 27 000]	
Totten *et al.* (2004)	Urban sites (Camden and Jersey City, New Jersey)	Sum of 116 congeners	Average, 3250 and 1260, respectively	
	Remote and suburban areas at various sites near the New York City metropolitan region		Averages of 150–220	
Sun *et al.* (2006)	Six sites near near USA–Canadian Great Lakes (Lake Michigan near Chicago)	Sum of 84 congeners	± 100–1400	
Hermanson & Johnson (2007)	Near the former Monsanto PCB-manufacturing facility in Anniston, Alabama	PCBs in tree bark	171 927 ng/g (ppb) lipid near the site, to 35 ng/g (ppb) lipid at a distance of 7 km	Tree bark serves as passive vapour-phase air sampler
Sun *et al.* (2007)	Six sites distant from urban areas near USA–Canadian Great Lakes (Lakes Superior and Huron)	Sum of 84 congeners	60–86	
	Six sites near near USA–Canadian Great Lakes (Lake Erie)		± 1.1–230	
Palmer *et al.* (2008)	Near the contaminated Hudson River, downstream communities	Sum of 84 congeners	Median, 711	Concentrations were higher closer to the river than further away, and higher in warmer than cooler months of the year. The congener pattern in air was primarily PCBs with three or four chlorines
	City upstream of the industrial sites that caused the contamination		Median, 431	
Palmer *et al.* (2008)	Contaminated portion of the Hudson River	Sum of 84 congeners	102–4011 (median, 711)	
	Community upstream of the contamination		80–2366	
Harrad *et al.* (2009)	Toronto, Canada	Sum of 8 congeners	100–1400 (mean, 350)	
Li *et al.* (2010)	North America	Sum of PCBs	79 (49–120)	
	Remote sites in Alaska and rural sites in the lower 48 states of the USA		1–50	
	Large urban areas like Chicago		1000 and 150 000	
Persoon *et al.* (2010)	Cleveland, Ohio	Sum of 151 congeners	1730–4240	
	Chicago, Illinois		1130–2690	

PCB, polychlorinated biphenyl

(2006) found large relative differences in air PCB concentrations between urban, rural and remote sites, with the highest concentrations in Toronto, Canada, and the Eastern third of the USA [absolute concentrations could not be quantified] using results from passive air samplers in 31 stations in Canada and the USA.

(b) Europe

In Europe, the reported PCB concentrations in outdoor air range from ~10 up to ~1000 pg/m^3 in western European countries and from ~50 up to ~9000 pg/m^3 in eastern European contries.

Measurement in the Baltic region showed PCB concentrations in southern Norway to be rather high and similar to those in urban areas (Backe *et al.*, 2000; Agrell *et al.*, 2001). Results from the Czech national monitoring system and European Monitoring and Evaluation Programme (EMEP) background monitoring stations also showed relatively high PCB concentrations in this country (EC, 2004). Typical values for background sites usually range up to ~100 pg/m^3 and up to several 100s pg/m^3 for contaminated areas (Kocan, 2000, 2001).

PCB concentrations in outdoor air may also be measured in precipitation as total deposition rates (ng/m^2 per day). In southern Sweden (Backe *et al.*, 2002), PCB concentrations ranged from 1.18 to 81.4 ng/L, with no seasonal trends. In Paris, France, average PCB concentrations (sum of seven congeners) in rain during 1986–2001 remained approximately constant at about 40 ng/L (Chevreuil *et al.*, 2001).

Declining concentrations of PCBs have been observed since the early 1960s and 1970s, decreasing by 67% in France (EC, 2004) and by 78% in the United Kingdom (CITEPA, 2013) over 20 years. The difference observed between the steady concentrations in rain and the decrease in general atmospheric emissions may be partly explained by water solubility limits and differences between point sources and global emissions.

Air concentrations of the seven indicator PCBs 28, 52, 101, 118, 153, 138 and 180 were measured at four locations in the Czech Republic, Finland, Sweden, and the Netherlands, from 1996 to 2001. Measured values did not vary noticeably during this period at any location (Fig. 1.6). This suggests that a steady-state has been reached between degradation and environmental cycling, with an ongoing low-level input from existing equipment and contaminated material (Holoubek *et al.*, 2003).

(c) Asia

Limited information on the concentrations of PCBs in air and dust has been reported in Asian countries (Table 1.17). One of the most extensive studies reported results for outdoor air samples from 55 sites in Japan, 20 in China, 30 in the Republic of Korea, and 1 in Taiwan, China. The range of concentrations was 100–1000 pg/m^3.

(d) South and Central America

Shen *et al.* (2006) found large relative differences in air PCB concentrations between urban, rural and remote sites using passive air samplers in 4 stations in Mexico, Belize, and Costa Rica. One site in Mexico had higher concentrations than sites in Central America and in Canada.

Li *et al.* (2010) reviewed information from various research groups around the world and reported the average concentration of the sum of PCBs in air to be 66 pg/m^3 (range, 9–670 pg/m^3) for South America, and 59 pg/m^3 (range, 17–150 pg/m^3) for Central America.

(e) Africa

Only recently have data from passive air samplers deployed on the African continent become available. PCB concentrations have been reported as very high in Senegal (500 pg/m^3) (Klánová *et al.*, 2009), Côte d'Ivoire, and the Gambia (up to 300 pg/m^3) (Gioia *et al.*, 2011). Concentrations in some areas in South Africa, Kenya, Egypt, the Democratic Republic of the

PCB_7, sum concentration of PCB-28, PCB-52, PCB-101, PCB-118, PCB-153, PCB-138, and PCB-180
From Holoubek *et al.* (2003)

Congo, Ghana, Mali, and the Sudan were also high, and comparable to those in urban areas in more developed countries. These levels could not be explained by biomass burning or primary emissions, and were probably due to e-waste dumps. Lower concentrations have been measured in the Congo, Ethiopia, Mauritius, Nigeria, the Togolese Republic, Tunisia, and Zambia.

(f) Vegetation used for monitoring studies

Plant foliage is a reliable proxy for monitoring levels of vapour-phase compounds in outdoor air since it bioaccumulates organic pollutants. Several researchers have used vegetation, grass, conifer needles, mosses, pollen, and leafy vegetable species (cabbage and lettuce) as biomonitors to evaluate patterns of PCB contamination (Larsen *et al.*, 1985; Reischl *et al.*, 1989; Kylin, 1994; Simonich & Hites, 1995). This method has been employed in high-mountain ecosystems (Daly & Wania, 2005), and in several countries, including the Czech Republic (Holoubek *et al.*, 1994), Poland (Migaszewski, 1999), western Finland (Sinkkonen *et al.*, 1995), Germany (Reischl *et al.*, 1987), Italy (Gaggi *et al.*, 1985), and France (Granier & Chevreuil, 1992).

1.4.4 Indoor air

PCBs have been shown to migrate into surrounding materials, such as concrete or wood, and to indoor air. The major sources are PCB-containing caulk, paint (where PCB-11 is the main marker), floor sealants, and ballasts

Table 1.17 PCB concentrations in outdoor air and dust in Asian countries

Reference	Country, region Date of study	Sources	PCBs measured Comments	Concentrations
Iwata *et al.* (1995)	Russian Federation, Lake Baikal May 1992	Six outdoor air samples from research vessel	Kanechlors 300, 400, 500, 600 as standards	Range, 8.7–23 pg/L
McConnell *et al.* (1996)	Russian Federation, Lake Baikal June 1991	A total of 19 outdoor air samples	Aroclors 1242 and 1254 as standards	Mean, 196 ± 65 pg/m^3
Hogarh *et al.* (2012)	Taiwan, China; China; Japan; Republic of Korea March–May, 2008	Outdoor air samples from 55 sites in Japan (37 rural, 4 suburban and 14 urban), 20 in China (3 rural and 17 urban), 30 in the Republic of Korea (12 rural, 2 suburban and 16 urban), and 1 in Taiwan, China	Sum of 202 congeners	Japan, 40–760 pg/m^3 China, 300–2500 pg/m^3 Taiwan, China, about 317 pg/m^3 Republic of Korea, 36–600 pg/m^3
Thacker *et al.* (2013)	India, central and western regions 2009–2010	Outdoor air samples from various cities	Sum of dioxin-like PCBs	Range, 0.0001 × 10^{-1} to 0.0295 ng TEQ/Nm^3

PCB, polychlorinated biphenyl; TEQ, toxic equivalent

in lighting devices. Outgassing from contaminated dust may also contribute. Joint sealants are increasingly recognized as important diffuse sources of indoor air contamination by PCBs.

(a) North America

PCBs have been measured in indoor air in several studies (Vorhees *et al.*, 1997; Vorhees *et al.*, 1999; Herrick *et al.*, 2004; Colt *et al.*, 2005; Franzblau *et al.*, 2009; Harrad *et al.*, 2009). In the USA it was reported that indoor air concentrations of PCBs were 5–300 times greater than those in outdoor air (Wallace *et al.*, 1996), and that concentrations were higher in older buildings. The concentrations of PCBs in indoor air in North America are summarized in Table 1.18.

(b) Europe

The highest indoor concentrations (up to 7500 ng/m^3) have been reported in buildings constructed between 1960 and 1975 from prefabricated concrete elements sealed with elastic materials containing PCBs (Balfanz *et al.*, 1993). Joint sealants containing PCB were discovered in various public buildings in Europe (Kohler *et al.*, 2005; Wilkins *et al.*, 2002). Estimated indoor PCB concentrations in contaminated sections were the lowest in microenvironments such as cars (8.92 ng/m^3), and were inversely related to the degree of chlorination of the PCB mixtures used (Hammar 1992; Harrad *et al.*, 2006; Kuusisto *et al.*, 2006, 2007; Frederiksen *et al.*, 2012). The concentrations of PCBs in indoor air in Europe are summarized in Table 1.19.

(c) Asia

Indoor floor dust samples (n = 43) collected from rural homes and mosques in Gujarat, Pakistan, showed median total PCB concentrations of 0.67 ng/g (range, 0.3–6.1 ng/g) (Ali *et al.*, 2012). The PCB profile was dominated by PCB-153 (> 60% of the sum of PCBs), with concentrations between < 0.2 and 2.4 ng/g. These PCB concentrations were 10 times lower than those reported in house dust in Singapore (Tan *et al.*, 2007).

1.4.5 Soil and sediments

PCBs can enter soil and sediments through various routes. Sediments constitute an important sink for PCBs entering the marine environment. Sewage sludges are monitored for PCBs in countries where they are largely used (60%) in agriculture. The dumping of incinerator-related materials and/or the inadequate management of commercial PCBs have resulted in significantly elevated PCB concentrations.

1.4.6 Water

Inputs of PCBs to the hydrological cycle are principally via discharges of sewage and industrial effluents, urban run-off, leachates from solid waste landfill sites, atmospheric deposition and, of increasing concern, via agricultural run-off (Scrimshaw *et al.*, 1996).

Water can contain PCBs either in solution or bound to particulates. While PCBs are not very water-soluble, water can be a significant source of exposure to less chlorinated congeners that have a greater solubility than more highly chlorinated congeners. PCB concentrations in sea and freshwater are summarized in Table 1.20.

(a) North America

(i) Drinking-water

In the USA, the EPA has set a goal for PCBs in drinking-water of zero, and a maximum contaminant concentration of 500 ng/L (500 ppt), with sources being primarily landfills, and discharge of waste chemicals (EPA, 2014). While conventional treatment of drinking-water will remove particulate-bound PCBs, those that are soluble are often not completely removed. Solubilities of individual PCB congeners vary from about 4 ppm for monochlorobiphenyl to as low as 0.0007

Table 1.18 PCB concentrations in indoor air in North America

Reference	Location	Source	PCBs measured	Concentration	Comments
Vorhees *et al.* (1997)	New Bedford Harbor, Massachusetts, USA	18 homes	Sum of 65 congeners	Geometric mean concentration, 18 ng/m³ (range, 7.9–61 ng/m³)	
		Comparison neighbourhood		Geometric mean concentration, 10 ng/m³ (range, 5.2–51 ng/m³)	
Vorhees *et al.* (1999)	New Bedford Harbor, Massachusetts, USA	House dust in homes surrounding the Superfund site	Sum of 65 congeners	1400 (range, 320–23 000) ng/g dry weight	
		Comparison neighbourhood		60 (15–290) ng/g	
Herrick *et al.* (2004)	Greater Boston, USA	24 university buildings		> 36 200 ppm 111–395 ng/m³	One third of the 24 buildings investigated contained caulk at concentrations > 50 ppm (the EPA limit)
Colt *et al.* (2005)	Four geographical regions in the USA	PCBs in carpet dust, 443 homes of Caucasian Americans who served as controls in a case–control study on non-Hodgkin lymphoma		Specific concentrations not reported	PCB concentration in dust was significantly related to age of the house, being greatest in homes built before 1940, and significantly greater in homes built in 1960–1979 (when PCBs were being manufactured in the USA) than in homes constructed after 1980
Franzblau *et al.* (2009)	Five counties in Michigan, USA	House dust House dust	PCB-123 PCB-118	439 000 ppt 33 600 000 ppt	Dioxin-like PCBs contributed 66.2% of the total WHO TEQ found in dust
Harrad *et al.* (2009)	Texas, USA	20 homes	Sum of 9 tri- to heptachlorinated congeners	200 ng/g (ppb); (range, 0.71–620 ng/g)	
	Toronto, Ontario, Canada	10 homes	Sum of 9 tri- to heptachlorinated congeners	260 ng/g (ppb) (range, 51–820 ng/g)	Levels were more than four times higher than those measured in cities in the United Kingdom and New Zealand

EPA, United States Environmental Protection Agency; PCB, polychlorinated biphenyl

Table 1.19 PCB concentrations in indoor air in Europe

Reference	Country	Source	PCB concentration (mean or range)	Comments
Hammar (1992)	Sweden	Joint sealants	80 ng/m^3	Outside the building, mean concentrations were 0.5–4.6 ng/m^3
Balfanz *et al.* (1993)	Germany	Air from contaminated buildings	Range, > 300–7500 ng/m^3	Indoor PCB concentrations were inversely related to the degree of chlorination of the PCB mixtures used
Wilkins *et al.* (2002)	Denmark (Organization of Sealant Branch's Manufacturers and Distributors)	Dust from public and residential buildings with excessive microbial growth	Estimated inventory of 75 tonnes in caulking materials	Concentration in polluted buildings was 10–20 times higher than the amount found in samples from other buildings
Kohler *et al.* (2005)	Switzerland	Joint sealants in public buildings	> 10 g/kg in 48% of samples	70% of samples contained PCB mixtures such as Clophen A50, Aroclor 1248, and Aroclor 1254
Harrad *et al.* (2006)	United Kingdom	Homes, offices, cars, public microenvironments	8.92 ng/m^3	The least contaminated microenvironment was the car (average, 1391 pg/m^3)
Kuusisto *et al.* (2007)	Finland	Walls/floor	110–540 µg/m^2	Detected PCBs were highly chlorinated
Frederiksen, *et al.* (2012)	Denmark	Air from uncontaminated apartments Elastic sealants from contaminated apartments	168–3843 ng/m^3 187–221 680 mg/kg	Significant correlations were observed between the lower chlorinated congeners in air and sealant

PCB, polychlorinated biphenyl

Table 1.20 PCB concentrations in various types of water around the world

Reference	Type of water	Location	PCB measured	Concentration	Comments
North America					
Jeremiason *et al.* (1994)	Lake	Lake Superior, USA		2.4 ng/L in 1980; 0.18 ng/L in 1992	
Connolly *et al.* (2000)	River	Hudson River		Sometimes > 1300 ng/L	Varied greatly with season and water flow
Rowe *et al.* (2007)	River	Delaware River	Sum of 116 congeners	420–1650 pg/L	
Wang *et al.* (2012)	River	Mississippi River	Sum of 27 congeners	86 and 254 ng/L	
	Lake	Lake Pontchartrain		134–728 ng/L	In some months the PCBs in river water were primarily in the liquid phase, whereas in other months primarily in the sediment
South and Central America					
Rissato *et al.* (2006)	River	Sao Paulo State, Brazil	Sum of seven congeners	0.02–0.5 ng/L	Predominantly lower chlorinated congeners
Africa					
Scarpato *et al.* (2010)	Sea	Tunisia Morocco–Algeria coastal sites	Sum of 10 congeners	10–12 ng/g 7–8 ng/g	PCB contamination evaluated by mussel-caging technique (exposure, 12 weeks)
Jayed *et al.* (2010)	Ocean	Thirteen sites along the Atlantic Moroccan coast	Sum of PCB-28, PCB-153, PCB-138	Wet season: 11 ng/g Dry season: 8.2 ng/g	Concentrations in mussels during wet and dry seasons not significantly different, but values in the northern sites exceeded 2–3 times the medians registered for the other sampling sites
Vorkamp *et al.* (2010)	Ocean	Cape Town harbour Cape Town sea shore Ghana coast	Sum of congeners	81 ng/g dw 15 ng/g dw 5 ng/g dw	Bivalve samples
Europe					
Nondek & Frolikova (1991)	Lake	Sumava lakes, Czech Republic		1900 ng/g	Contamination due to atmospheric transport to non-industrialized areas
Winkels *et al.* (1998)	River	River Danube, Czech Republic		< 5 ng/g dw	Contamination due to flood disaster in the Moravian part of the Czech Republic in July 1997

Table 1.20 (continued)

Reference	Type of water	Location	PCB measured	Concentration	Comments
Fillmann *et al.* (2002)			Sum of seven congeners	≤ 700 ng/g dw (2–196 µg/kg ww in fish)	
UNEP (2002)	River	Krupa, Sana and Lepenica rivers, Balkan area, Slovenia		380 ng/L (in 1988) 100 ng/L (in 1997)	The factory in Semič was storing 5–6 tonnes of waste oil containing PCBs
Desmet *et al.* (2012)	River	Rhone river, France	Sum of PCB_7	1–40 ng/g dw	Concentrations consistently lower than those found during the previous decade (Burns & Villeneuve, 1987). Maximum PCB concentration was identified in 1960–75. The downward trends in concentration followed emission reductions, although soil concentrations decreased at much slower rates (Tolosa *et al.*, 1995)
ADEME (1998), Blanchard *et al.* (2001)	Wastewater	Wastewater treatment plants, France	Sum of seven congeners	Input water, 100–300 ng/L Output water, 15–54 ng/L	In 1999, average concentration was 15–26 ng/L. High levels of DL-PCBs in eel from Dutch freshwater were reported in a screening of Dutch fishery products (Van Leeuwen *et al.*, 2002)
Asia					
Kucklick *et al.* (1994)	Lake	Lake Baikal, Siberia, the Russian Federation, June 1991	61 PCB congeners using standards of Aroclor 1242, 1254, and 1260	Mean, 560 ± 180 pg/L for dissolved phase, and 420 ± 400 pg/L for particulate phase	
Iwata *et al.* (1995) May 1992	Lake	Lake Baikal, the Russian Federation, June 1991	Kanechlors 300, 400, 500, 600 as standards	Range, 8.7–23 pg/m^3	
McConnell *et al.* (1996) June 1991	Lake	Lake Baikal, the Russian Federation, June 1991	Aroclors 1242, 1254 as standards	Mean, 1 324 ± 96 pg/m^3	

DL-PCB, dioxin-like polychlorinated biphenyl; dw, dry weight; PCB, polychlorinated biphenyl; ww, wet weight

ppm for the decachlorobiphenyl (Erickson, 1997). Thus under certain circumstances, drinking-water can still be a source of exposure to less chlorinated congeners.

(ii) Sea and freshwater

The USA–Canadian Great Lakes are contaminated by multiple sources of PCBs (Bhavsar *et al.*, 2007; Turyk *et al.*, 2012). It has been shown that industrial sites on rivers feeding Lake Erie received the largest quantities of PCBs, with 26% derived from atmospheric deposition (Kelly *et al.*, 1991). The Hudson River in New York is highly contaminated with PCBs because of releases from two large capacitor plants (Carpenter & Welfinger-Smith, 2011), the Fox River in Wisconsin is highly contaminated because of releases from a manufacturer of carbonless copy paper, and a paper mill (Imamoglu *et al.*, 2004), and the St Lawrence River and several of its tributaries have been contaminated by releases from aluminium foundries operated by companies that discarded hydraulic fluids containing PCBs in drains (Fitzgerald *et al.*, 1996). The Hudson and Fox Rivers are being dredged to remove these contaminants.

(b) Europe

(i) Sea

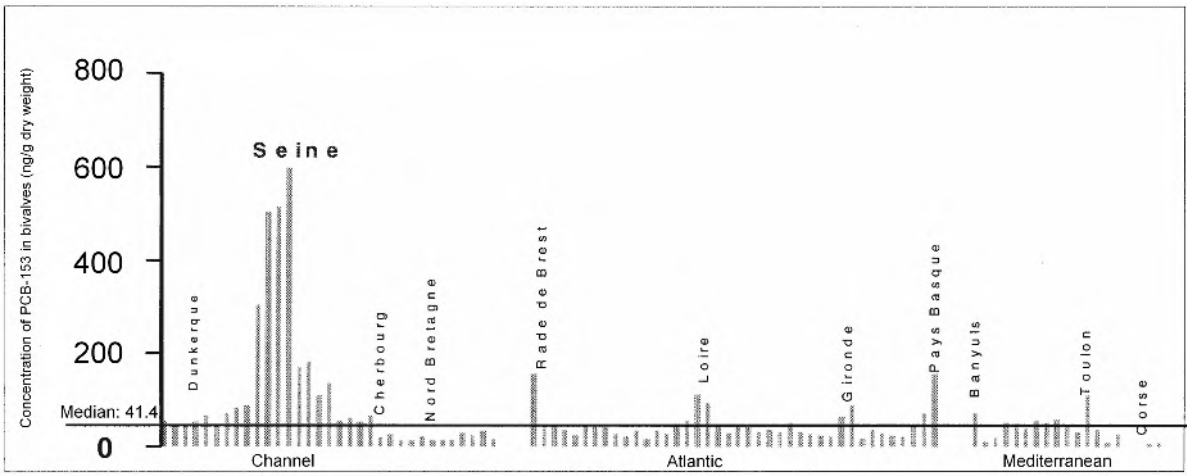
An extensive review of data obtained during the 1980s has been published (Tolosa *et al.*, 1995). In general, the concentrations of PCBs for all the investigated areas in the Mediterranean Sea were similar except in the Ligurian Sea where concentrations were higher. Predictably, the highest concentrations were reported in urban and industrial wastewaters (e.g. from Marseille and Barcelona) as well as in river discharges (e.g. from the Rhone), and decreasing concentration gradients have been found in transects offshore from these sources. PCB concentrations in the suspended particulate matter from coastal and open Western Mediterranean waters were of 5–35 pg/L in 1990, of the same order of magnitude as those reported in other regions, e.g. North Sea and North Atlantic. A more recent study covering the whole Western basin also shows a spatial gradient from the continental shelf (3.5–26.6 pg/L) towards the open sea (1.7–6.6 pg/L); a relatively important enrichment (8.4 pg/L) in open sea stations located in higher productivity frontal zones was observed (Dachs *et al.*, 1997). The dissolved PCBs (Σ12 congeners) amounted to 28–63 pg/L. Total concentrations of PCBs in estuarine and coastal sediment samples of the Mediterranean Sea ranged from 0.04 to 1684 ng/g dw (Koci, 1998; Vale *et al.*, 2002; Vojinovic-Miloradov *et al.*, 2002; Cardellicchio *et al.*, 2007).

During 1974–82, PCB concentrations decreased by a factor of 3 in offshore Monaco (Burns & Villeneuve, 1987), while the surface sediments of the Adriatic coast did not show a temporal trend (Picer & Picer, 1991).

Concentrations of PCBs in ocean water are usually in the low picogram per litre range. The general trend for concentrations in the Baltic Proper suggests an increase in PCB concentrations from the early 1970s onwards (ICES, 2000). This is an opposing trend to the decreasing concentration trends for PCBs in biota from the Baltic Proper (HELCOM, 1996; Roots, 1996).

The monitoring of PCBs in coastal areas may be based on measurements in mussels. Trends in PCB concentrations in the Seine estuary in France are reported in Fig. 1.7 (RNO, 2012). The rate of decrease was 3.5% per year. As reported by the Arctic Monitoring and Assessment Programme (AMAP), several time-series of PCB-153 concentrations in blue mussels from around Iceland showed significant decreasing trends; however, one time-series from a fjord system showed a significant increase (Rigét *et al.*, 2010). Active mussel watching (mussel transplantation) has also been applied in monitoring programmes in Africa (see Table 1.20).

Fig. 1.7 PCB contamination along the coast of France



Concentrations of PCB-153 in mussels or oysters (used as "sentinel species") sampled from coastal areas of France. The Seine estuary and bay are heavily exposed to manmade chemicals of terrestrial origin derived from the urbanized and industrialized river Seine.
Data from The French pollution monitoring programme (Réseau National d'Observation de la qualité du milieu marin)
Reproduced from Abarnou *et al.* (2002), with permission from the publisher

(ii) Freshwater

The major source of freshwater contamination in Europe comes from diffuse leaching of products from users, households, and industries into wastewater streams (UNEP, 2002). The areas most polluted by flood disasters are in Poland (the River Odra) (Wolska *et al.*, 1999; Protasowicki *et al.*, 1999) and in the Czech Republic. The River Danube is a major source of contamination to the Black Sea; however, many chlorinated hydrocarbons have been banned by several European and other countries in the past 10 years (Winkels *et al.*, 1998; Covaci *et al.*, 2002c; Fillmann *et al.*, 2002; see Table 1.20).

Industrial contamination is known to have occurred in Germany (the Rivers Elbe and Rhine and their tributaries) (Brauch, 1993), in former Czechoslovakia (the Sumava Lakes) (Nondek & Frolikova, 1991), in England and Ireland (where however approximately a 50% decline in concentrations between 1970 and 1990, was recorded) (Sanders *et al.*, 1992; Harrad *et al.*, 1994) and in Slovenia through the dumping of industrial waste in the Krupa river during the manufacture of transformers. PCB contamination also occurred in the Balkan area, in the cities of Pancevo, Novi Sad, Belgrade, Kragujevac, in Serbia, after military intervention by NATO in spring 1999.

1.4.7 Food products

Since the early 1990s, food has been identified as the major route of human exposure to lipophilic and persistent organochlorines such as PCBs, PCDDs, and PCDFs. In populations that are not exposed to other known sources, dietary intake contributes to about 90% of the total daily intake of dioxin-like compounds including dioxin-like PCBs, and of this, food of animal origin contributes about 90% in various regions of the world (Schecter *et al.*, 1997; Büchert *et al.*, 2001; Llobet *et al.*, 2003a, b; Päpke & Fürst, 2003; Schecter *et al.*, 2003a, b; Charnley & Doull, 2005; Huwe & Larsen, 2005).

Similarly, it is generally accepted that the major route of exposure to non-dioxin-like PCBs, namely to PCB_6, is dietary intake, by consumption of fatty foodstuffs (IARC, 1978; IPCS, 1993; EFSA, 2005; Lindell, 2012). However, inhalation can also be a significant source of exposure (see Section 1.4.4).

Human food can become contaminated by PCBs via three main routes:

- uptake from the environment, by fish, birds, livestock (via food-chains), and crops;
- contamination of animal feed, by regular practices or accidentally;
- direct contamination of food, accidentally.

Data on PCB concentrations in food are reported in many different ways, making comparisons difficult. The number of congeners analysed differs between studies and often congeners are summed according to groups, such as indicator PCBs, DL-PCBs, or some other number of congeners. When using TEQs, the scheme used should be noted; also some studies report TEQ on the basis of bioassays such as the CALUX system as biological equivalents (BEQ). Results have been reported with different reference units (wet weight, dry weight, or lipid weight). Further difficulties in interpretation arise since different parts of fish or seafood are analysed (muscle, liver, skin, etc.) and PCB concentrations are also sometimes reported on the basis of prepared food (to account for changes by cooking or frying). Finally, the objectives of a study may bias the sampling strategy, often resulting in reporting of higher concentrations.

(a) PCB concentrations in food

Concentrations of DL-PCBs in various meats and dairy products from selected countries and regions are presented in Table 1.21.

(i) Polar regions and North America

PCB concentrations in food for polar regions and North America are summarized in Table 1.22. Domingo & Bocio (2007) reviewed the concentrations of PCB and PCDD/PCDF in marine species and human intake through fish and seafood consumption by different region-specific sections.

The traditional food items for indigenous peoples in the Arctic include lipid-rich tissue of high trophic-level animals. After long-range transport and biomagnification of PCBs in the Arctic marine food-chain, PCBs accumulate in edible animals like fish, seals and whales (AMAP, 2004). This dietary exposure led to PCB concentrations in Arctic inhabitants that exceeded those of individuals living at temperate latitudes (Dewailly *et al.*, 1993), but levels have been shown to decrease (AMAP, 2009). Likewise, PCBs in traditional food items have generally decreased (Rigét *et al.*, 2010).

(ii) Africa

Loutfy *et al.* (2006) investigated levels of WHO-TEQs from diet in Egypt, and determined a range of 6.59–9.98 pg TEQ/kg per day, with about 40% of this value due to DL-PCBs. This value exceeds the maximum WHO tolerable daily intake (TDI) of 4 pg TEQ/kg per day. The primary source was found to be dairy products, in which PCB concentrations were several times higher than in such products in more developed countries. Loutfy *et al.* (2007) determined the concentrations of PCDD/PCDF and dioxin-like PCBs in samples of fish and seafood (mullet fish, bolti fish, bivalves and crab) randomly acquired in local markets in Egypt. The upper-bound concentrations of dioxin-like PCBs ranged from 0.14 (bivalves) to 0.76 (mullet) pg WHO-TEQ/g wet weight, respectively.

Adu-Kumi *et al.* (2010) reported an average TEQ for dioxin-like PCBs in fish from two lakes in Ghana to be 0.7 pg WHO-TEQ/g.

(iii) Australia and New Zealand

In 2000–2001, 168 samples of 22 foods collected for the Australian Total Diet Survey were analysed for DL-PCBs and compared with those from other areas of the world (Table 1.21; Food Standards Australia New Zealand, 2004).

A more recent study reported PCB concentrations from composite samples of Australian farmed yellowtail kingfish (mean, 21 µg/kg; range, 8.6–29 µg/kg), mulloway (mean, 5.4 µg/kg; range,

Table 1.21 Concentrations of dioxin-like PCBs in selected foods from various countries and regions

Food	PCB concentration (range of means), pg TEQ/g lipid					
	Australia	Europe[a]	New Zealand[a,b]	North America[a]	Netherlands[c]	United Kingdom

PCB, polychlorinated biphenyl; TEQ, toxic equivalent

4.7–6 µg/kg) and manufactured feed (Padula *et al.*, 2012). The mean concentration of DL-PCBs was 2.1 pg TEQ/g (range, 1.2–2.8 pg TEQ/g) in kingfish, and 0.51 pg TEQ/g (range, 0.41–0.61 pg TEQ/g) in mulloway.

(iv) Asia

Concentrations of specific PCB congeners in samples of food from Asia are summarized in Table 1.23. In Japan, a study sponsored by the Ministry of Health and Welfare showed a more than 50% decrease in concentrations of three non-*ortho* substituted PCBs in human milk samples between 1973 and 1996 (Environment Agency of Japan, 1999). A report from the Republic of Korea demonstrated regular dietary exposure (Son *et al.*, 2012; Table 1.23). In China, Liu *et al.* (2011) determined concentrations of seven indicator PCBs in marine fish. The sum of PCB_7 ranged from 0.3 to 3.1 µg/g wet weight, with median and mean values of 6.4 ng/g wet weight and 398 ng/g wet weight, respectively (Table 1.23). The average concentrations and contributions of the seven specific congeners at four different sites are presented in Table 1.24. [It was noted that the concentrations found in this study were higher than in other parts of the world.]

(v) Europe

The major contributors to total exposure in Europe appeared to be milk and dairy products for almost all groups of infants and toddlers (Barr *et al.*, 2006; Becker *et al.*, 2009), and fish and seafood products for most of the adolescents, adults, elderly and very elderly groups (Langer *et al.*, 2007; Fréry *et al.*, 2009; ANSES, 2011).

The most comprehensive assessment of PCB concentrations in food was undertaken by the European Food Safety Agency (EFSA) (EFSA, 2005, 2010, 2012). For the 27 European Union Member States, and Switzerland and Norway, in a report that took all food groups together, the

Table 1.22 PCB concentrations in marine foods and estimated dietary intake in polar regions and North America

PCB, polychlorinated biphenyl; ww, wet weight
Data from Liu *et al.* (2011)

upper bound (lower bound) for the 50th, 90th and 95th percentiles were < 0.005 (< 0.005), 0.02 (0.01) and 0.03 (0.01) pg WHO_{2005}-TEQ/g wet weight for PCDD/PCDF, respectively. For the total TEQ, the upper bound (lower bound) concentrations were 0.01 (< 0.005), 0.04 (0.02) and 0.07 (0.04) pg WHO_{2005}-TEQ/g wet weight, respectively (EFSA CONTAM, 2012). Infant formulae showed upper bound concentrations below the current maximum levels (0.2 pg WHO_{2005}-TEQ/g wet weight), with highest concentrations found in ready-to-eat meals containing fish or meat. Overall, a decrease in concentrations of DL-PCBs was observed for the three food groups available: "raw milk and dairy products," "hen eggs and egg products" and "muscle meat from fishes other than eels." Feed and food of animal origin contained higher concentrations of PCDD/PCDF and DL-PCBs combined (the non-*ortho* PCBs were the main contributors to the total TEQs) than foods from plant origin. PCB-153, PCB-138, and PCB-180 represented altogether 36.9–97.8% of the sum of PCB_6. The maximum levels were exceeded in 9.7% of the food samples and 2.3% of the feed samples for PCDD/PCDF and DL-PCBs combined, and in 3.0% of the food samples and 2.4% of the feed samples for the PCB_6. With respect to food categories, lower PCB concentrations were found in meat from sheep, eggs from battery rearing, farmed salmon and trout, and farm milk (which however showed higher concentrations of PCDD/PCDF and DL-PCBs combined than milk from bulk) (EFSA, 2012).

The Baltic Sea area is heavily contaminated with persistent organochlorine compounds, including PCBs (Kiviranta *et al.*, 2003), as is clearly attested by samples of fatty fish from the eastern coast in Sweden (Svensson *et al.*, 1995). In the most contaminated feed group, the highest relative contribution to the WHO_{2005}-TEQ_{total} came from non-*ortho* PCBs, up to twice the average contribution (EFSA, 2012).

(b) Estimated daily dietary intake

In Europe, more than 90% of PCB exposure in the general population is via food consumption (EFSA, 2005; Table 1.25). Average daily dietary intakes of the sum of PCB_6 are in the range of 10–45 ng/kg bw for adults, and two and a half times higher in children. Limited exposure data for young children indicate that the average daily intake (breastfeeding excluded) of the sum of PCB_6 is about 27–50 ng/kg bw. Overall, the non-*ortho* PCBs represented 21.0–74.9% of the WHO_{2005}-TEQ_{total} of PCDD/PCDF and DL-PCBs combined in food (EFSA, 2012), and the mono-*ortho* PCBs represented no more than 12% of the WHO_{2005}-TEQ_{total}. In the most contaminated samples, such as products from aquatic animals and from ruminants, the relative contribution of the non-*ortho* PCBs ranged from 34.2% to 86.1%. Most likely due to an effect of the European risk management measures, a decrease in exposure to the sum of PCB_6 was observed between 2002–2004 and 2008–2010 in most but not all population groups, and it was estimated between 2.0% and 75.6%.

In the USA, the daily dietary intake of PCBs for adults decreased from 1978 (0.027 µg/kg bw) until 1986–1991 (< 1 ng/kg bw) (IPCS, 2003). Mean daily intakes for infants during the same period decreased from 11 to < 1 ng/kg bw. However, trends during 1991–1997 did not appear to decrease, and ranges of daily dietary intake were 3–5 ng/kg bw for adults, and 2–12 ng/kg bw for children of different ages (IPCS, 2003).

Daily dietary intake of PCBs from countries in Asia are presented in Table 1.26. In China, the estimated daily intake from four food groups of animal origin ranged from 0.09 to 0.59 pg TEQ/kg bw for DL-PCBs, which is lower than the daily intake in some developed countries (Liu *et al.*, 2013). A survey of food items on the market and typical consumption patterns in Japan reported a daily intake for the general population of 2.60 pg TEQ/kg bw per day (Koizumi *et al.*, 2005). Of

Table 1.26 Estimated daily dietary intake of PCBs in Asia

Country, region	Date	Source	PCBs measured	Mean daily intake	Reference
Japan, Fukuoka Prefecture	1969–70	Patients Individual consumption of oil was estimated by taking into account age, sex and the number of meals at home	PCBs, PCDFs, and PCQs	Estimated total intake: PCBs, 633 mg PCDFs, 3.4 mg PCQs, 596 mg	Hayabuchi *et al.* (1979)
Japan, eight sites from Hokkaido to Okinawa	1995 survey	Food duplicate study 40 women (mean age, 52 years)	11 PCB congeners (74, 99, 118, 138, 146, 153, 156, 163, 170, 180, and 182)	165.9 ng/day	Koizumi *et al.* (2005)
Japan, 75 different areas of 25 prefectures	Not reported	Food duplicate study 374 subjects, 86 men and 288 women (mean age, 48.0 years; range, 17–72 years)	12 PCBs	Mean PCB intake, 0.59 pg/kg bw per day Median PCB intake, 0.39 pg/kg bw per day	Arisawa *et al.* (2008)
Republic of Korea	2010	Estimated dietary intake 200 individual food samples from 40 different foodstuffs	62 PCB congeners, including 7 indicator PCBs and 12 DL-PCBs (PCB-1, 3, 4, 8, 10, 15, 18, 19, 22, 33, 37, 44, 49, 54, 70, 74, 87, 95, 99, 104, 110, 112, 128, 149, 151, 155, 158, 168, 170, 171, 177, 178, 183, 187, 188, 191, 194, 199, 201, 202, 205, 206, 208, and 209)	9.9 ng/kg bw per day	Son *et al.* (2012)

DL-PCBs, dioxin-like polychlorinated biphenyls; PCDFs, polychlorinated dibenzofurans; PCQs, polychlorinated quaterphenyls; ww, wet weight

these, 2.41 pg TEQ/kg bw per day was from ingestion of food, while inhalation and soil ingestion contributed only to 0.19 pg TEQ/kg bw per day. A "typical" Japanese person receives 120.7 pg TEQ per day through food consumption (mainly fish/shellfish, followed by meat/eggs).

In specific subpopulations with high dietary PCB exposure, such as Baltic Sea fishermen, the daily intake from fish of the sum of PCB_6 was estimated at 40 ng/kg bw, corresponding to a total daily intake of the sum of non-dioxin-like PCBs of 80 ng/kg bw, before taking into account the rest of the diet (Lindell, 2012).

In breastfed infants, the most recent WHO study of PCB exposure reported a mean daily intake of about 1600 ng/kg bw (range, 230–7300 ng/kg bw per day) for total PCB_6. Thus, exposure of infants to PCB_6 (and DL-PCBs) through human milk is about two orders of magnitude higher than the average daily intake by adults.

1.4.8 Occurrence in manufactured products other than commercial PCB preparations

In addition to commercial PCB preparations, many manufactured products contain PCBs as a result of contact with PCB products, as contaminants during manufacture, or as degradation products of other chlorinated compounds. For example, PCBs have been found in various paint pigments (Hu & Hornbuckle, 2010; Kuusisto *et al.*, 2006). Electronic equipment contains PCBs, which are released during dismantling.

Since the sampling and determination of the presence of PCBs is a difficult process, the Basel Convention has established a so-called "grey list" of materials and equipment that are suspected to contain PCBs (Basel Convention, 2003):

- Cable insulation
- Rubber and felt gaskets
- Thermal insulation material including fibreglass, felt, foam and cork
- Transformers, capacitors (also contained in electronic equipment)
- Voltage regulators, switches, bushings and electromagnets
- Adhesives and tapes
- Oil, including that contained in electrical equipment and motors, anchor windlasses, hydraulic systems
- Surface contamination of machinery and other solid surfaces
- Oil-based paint
- Caulking
- Rubber isolation mounts
- Foundations mounts
- Pipe hangers
- Light ballasts
- Plasticizers.

1.4.9 Population biomonitoring

(a) Blood

The presence of PCBs in serum or blood may reflect exposure from any source (Dewailly *et al.*, 1988). Results from different studies in humans have indicated that measurements of PCBs in serum generally reflect cumulative past exposure. Many PCB congeners can remain in the body for years after exposure, although some of the less chlorinated congeners are more volatile and consequently show shorter residence times.

(i) North America

Hopf *et al.* (2009a) provided an extensive review of reports on background levels of PCBs in the USA population. They concluded that serum concentrations increased up to 1979 and decreased after that, but that the background levels are still of concern. The NHANES survey over the period 2002–2004 reported increasing

concentrations of PCBs with age, and concentrations were higher in men than in women, and higher in African-Americans and Caucasians than in Mexican-Americans (Patterson *et al.* 2009). Sjödin *et al.* (2004) showed a decline in concentrations of PCB-153 between 1985 and 2002 in pooled samples from the NHANES study.

Several studies have looked at specific populations living near specific contaminated sites or eating contaminated fish (Table 1.27).

Serum concentrations for the sum of 17 congeners in Viet Nam veterans were 167.5 ng/L lipid adjusted, of which the major portion (116.6 ng/L) were di-*ortho* congeners (Schecter *et al.*, 1996).

Jarrell *et al.* (2005) determined the sum of 24 congeners in pregnant women in Canada, and reported a mean value of 0.78 ng/L wet weight.

Because the less chlorinated PCBs are more volatile, teachers working in a school where caulk containing PCBs was used showed serum congener profiles that were enriched in less chlorinated congeners (Herrick *et al.*, 2011).

DeCaprio *et al.* (2005) reported finding a pattern of PCB congeners in serum specific of young native Americans living near a PCB-contaminated waste site. This pattern was not clearly observed in older individuals because it was obscured by the greater concentrations of more persistent congeners, coming primarily from dietary exposure.

(ii) Europe

Several European studies on human biomonitoring have reported blood PCB concentrations in adults or children (summarized in Table 1.28). Past environmental contamination in industrial areas has polluted surrounding soils and forage, leading in turn to high blood PCB concentrations in the adult population. Age-related accumulation of PCBs has been observed in many studies (Patterson *et al.*, 1994; Apostoli *et al.*, 2005; Park *et al.*, 2007), and may be partially explained by historical high levels of exposure in the 1970s.

In Germany, Environmental Surveys (GerES) were carried out in 1998 (Becker *et al.*, 2002) and during 2003–2006 (Becker *et al.*, 2009). GerES data show mean blood concentrations for the sum of PCBs of 1.3–1.7 µg/L in 1998 and of 286 ng/L in the more recent survey, with strong difference (factor of 5.6) between age groups 18–25 and 66–69 years. In Belgium in 2007–2011 (Schoeters *et al.*, 2011), the Flemish Human Environmental Survey reported average blood PCB concentrations of 333 ng/g lipid. Average concentrations in the United Kingdom in 2003 were 170 ng/g lipid (Thomas *et al.*, 2006). In Spain in 2004–2008, concentrations of the most common PCBs were in the range of 21.8 to 38.9 ng/g lipid (Ibarluzea *et al.*, 2011). In France, blood analysis in the general adult population was first carried out in 1986 (Dewailly *et al.*, 1988) and then in 2006–2007 (French Nutrition and Health survey; Fréry *et al.*, 2013). The reported blood PCB concentrations in populations in industrial polluted areas such as Italy (Turci *et al.*, 2004; Apostoli *et al.*, 2005; Turrio-Baldassarri *et al.*, 2008) and Slovakia (Jursa *et al.*, 2006) were high compared with those in non-occupationally exposed populations such as in Sweden (Salihovic *et al.*, 2012). In the Faroe Islands (Denmark), high concentrations of PCBs and hydroxylated PCBs in serum samples from pregnant women were attributed to the traditional diet, made of pilot whale meat, blubber and other marine food (Fängström *et al.*, 2002).

The most frequently detected di-*ortho*-chlorine-substituted PCBs in population studies are PCB-138, PCB-153, and PCB-180 (Glynn *et al.*, 2000), accounting for 65–78% of the measured sum of total PCBs (Needham *et al.*, 2005). The seven PCB indicator congeners (118, 138, 153, 156, 170, 180, and 194) contributed to 99% of the total PCB levels, with a modest contribution from dioxin-like congeners (Apostoli *et al.*, 2005).

In several countries in the European Union, a clear decrease in blood concentrations of PCBs has been observed in the last two decades. Overall,

Table 1.27 Serum concentrations of PCBs after consumption of PCB-contaminated fish, North America

Country, region	Sample	PCBs measured	Mean ng/g (ppb)	Reference
North Canada, Nunavik	Inuit women, *n* = 159	Sum of 14 congeners	313.2 ± 2 Range, 71.3–1951.3	Muckle *et al.* (2001)
USA, St Lawrence River	Native American adults, *n* = 753	Sum of 101 congeners	4.39 ± 4.18	DeCaprio *et al.* (2005)
USA, St Lawrence River	Native American adolescents		0.71 ± 0.668 (if not breastfed) 0.95 ± 0.806 (if breastfed)	Schell *et al.* (2008)
USA, Great Lakes	Fish consumers, *n* = 293 Fishing-ship captains, men	Sum of 89 congeners in µg/L (ppb) wet weight	4.2 (2.7), in 1994–95 2.8 (2.0), in 2001–05 6.3 (5.0), in 1994–95 1.2 (0.9) – 3.8 (3.0), in 2001–05	Knobeloch *et al.* (2009)
USA, Anniston, Alabama	Adult residents, *n* = 394	Sum of 35 congeners	4.72 ± 11.05 Range, 0.09–170.42	Goncharov *et al.* (2011)

PCB, polychlorinated biphenyl

mean whole blood concentrations of PCB-138, PCB-153, and PCB-180 appear to have decreased by approximately 80% in 20 years (Link *et al.*, 2005; Hagmar *et al.*, 2006; Agudo *et al.*, 2009; AMAP, 2009). Nevertheless, compared with North America (CDC, 2005), serum concentrations of PCB-138, PCB-153, and PCB-180 were higher by two- to fivefold in Germany in 1998 (Heudorf *et al.*, 2002), or Italy in 2001–2003 (Turci *et al.*, 2004; Apostoli *et al.*, 2005; Needham *et al.*, 2005). Similarly, serum concentrations of hydroxylated PCBs and methylsulfonyl-substituted metabolites of PCBs were higher by two to threefold in a contaminated area in a study in Slovakia (Hovander *et al.*, 2006).

(iii) Asia

In Asia, PCB concentrations in several biological samples (including serum or whole blood, umbilical cord blood, hair, breast milk, adipose tissue, liver, kidney, and lung tissues) showed a wide range (Table 1.29; Schecter *et al.*, 2003a). Data specific to the Yusho and Yucheng patients are presented in Table 1.30 and Table 1.31, respectively.

(iv) South and Central America

Rodríguez-Dozal *et al.* (2012) analysed serum samples from pregnant women in Mexico for 19 congeners and Aroclor 1260. For Aroclor 1260 [calculated as the sum of PCB-138 and PCB-153 multiplied by 5.2], they reported regional differences (mean concentration, 31.1 ng/g lipid) and elevated concentrations from residents of Merida (maximum, 546.2 ng/g lipid). Trejo-Acevedo *et al.* (2012) measured serum PCB concentrations (sum of 14 congeners) from children living in a malaria-endemic area of Mexico, and reported a mean serum PCB concentration of 5892 ± 3895.7 ng/g lipid. In an analysis of PCB congeners in maternal blood of women in Sao Paulo State, Brazil, PCB-118, PCB-138, and PCB-153 were detectable in more than 70% of samples, and their concentrations were almost double in women from industrial areas compared with women from rural areas (Rudge *et al.*, 2012).

(v) Africa

Röllin *et al.* (2009) reported overall low blood concentrations of PCBs (99, 118, 138, 153, 170, 180 and 187) in delivering mothers from seven geographical regions in South Africa. Large regional differences were observed, with women

Table 1.28 Blood concentrations of PCBs in various European countries

Table 1.31 PCB concentrations in biological samples from Yucheng patients, Taichung County, Taiwan, China

Date of study	Patients	Sample	PCB measured	Concentration (mean, median, range)	Reference
1979–81	Children (n = 113)	Blood	PCBs	39 000 pg/g	Kashimoto *et al.* (1985)
1992	Mothers (n = 56)	Adipose tissue		2820 ± 300 (SE) ng/g	Guo *et al.* (1997)
1994–6	Adults (n = 42)	Sebum Blood	Dioxin-like PCBs	868.6 pg/g 714.4 pg/g	Iida *et al.* (1999)
1994	Adults (n = 414)	Serum	NR	1500 ng/g lipid (PCB-138 represented 29% of all measured PCBs)	Lung *et al.* (2005)
1994–5	Adults (n = 41)	Blood	NR	2468 ng/g lipid (13.3 ng/g sample) 133 pg/g (PCB TEQ in men) 127 pg/g (PCB TEQ in women)	Hsu *et al.* (2005) Lambert *et al.* (2006)

NR, not reported; PCB, polychlorinated biphenyl; SE, standard error; TEQ, toxic equivalent

from rural areas having the lowest levels of PCBs. PCB-138 and PCB-153 were found in the blood of mothers from all of the 61 sites studied at geometric mean concentrations of 3.56 and 3.2 ng/g lipid, respectively. Ahmed *et al.* (2002) reported the sum concentration of 29 congeners in blood from Egyptian women to be 61.9 ng/g. Weiss *et al.* (2006) reported concentrations of PCB-153 in infertile women in the United Republic of Tanzania to be 0.17 µg/kg. Sum PCB concentrations in serum samples from Bizerte, Tunisia, ranged from 37.5 to 284.6 ng/g lipid, with mean and median value of 136.1 ng/g lipid and 123.2 ng/g lipid, respectively. The PCB profile consisted mainly of persistent congeners such as PCB-138, PCB-153, and PCB-180 (82.7% of the sum of PCBs). PCB concentrations were significantly higher in men ($P < 0.05$) than in women (Ben Hassine *et al.*, 2014).

(b) Human milk

Due to its high fat content, human milk can accumulate large amounts of PCBs, thus making it an ideal matrix for the determination of concentrations of PCBs and other lipophilic compounds, and can be sampled using non-invasive techniques. In addition, human milk represents a good indicator of the body burden of lipophilic non-metabolized PCBs, since fat is mobilized for the production of milk during lactation. Animal studies and mass balance studies for humans have revealed that large amounts of PCBs can be eliminated through lactation (Lindell, 2012). Data are summarized in Table 1.32.

(i) Global assessment

The transfer of PCBs from mother to infants via breast milk is an important source of exposure, and several factors (including maternal residence, age, and parity) can potentially affect levels of contaminants in breast milk. Because of the importance of breastfeeding for infants, contamination of human milk is of specific public concern.

The Stockholm Convention on Persistent Organic Pollutants (POPs) is a guidance document, the objective of which is to document the effectiveness of the implementation of the obligations under the Convention. The World Health Organization (WHO) introduced worldwide measurement campaigns to determine the exposure of infants to dioxin-like PCBs (UNEP, 2012).

[a] Indicator PCBs are PCBs 28, 52, 101, 138, 153 and 180

DL-PCB, dioxin-like polychlorinated biphenyl; PCB, polychlorinated biphenyl; TEQ, toxic equivalent

The evaluation of the Stockholm Convention has been applied (with slight changes) for five rounds of the UNEP/WHO survey. Often, human milk from primiparae mothers (for detail, see UNEP, 2012) is preferred to human blood, since sampling is non-invasive and PCBs are easier to detect (due to the higher lipid content of milk). It should be noted that for global assessment, the concentrations of dioxin-like PCBs (DL-PCBs) on a TEQ basis for the last three rounds of the UNEP/WHO survey on mothers' milk may be lower by 30% (range, 2–60%) if WHO toxic equivalency factors (TEFs) for 2005 (WHO_{2005}-TEF) are applied, rather than those for 1998 (WHO_{1998}-TEF). International chemical assessments report that the average concentration of PCBs in human milk fat ranges from 0.5 to 4 μg/g (IPCS, 2003). For the sum of PCB_6, the median is between 10.8–30.7 ng/g lipid, and maxima are between 37.1–65.8 ng/g lipid. Overall, the UNEP/WHO survey showed a correlation between maternal age and concentrations of DL-PCBs in breast milk, and lower concentrations of PCBs in breast milk of multiparous women when compared with primiparous women.

(ii) Americas

The mean concentration of PCBs in whole breast milk in Canadian women steadily increased from 6 μg/kg in 1970 to 12 μg/kg in 1975, and to 26 μg/kg in 1982, before declining to 6 μg/kg in 1986 (IPCS, 2003).

Recent data on concentrations of PCDD/PCDFs and DL-PCBs in human milk from South America were reported only for Brazil (Paumgartten *et al.*, 2000).

(iii) Europe

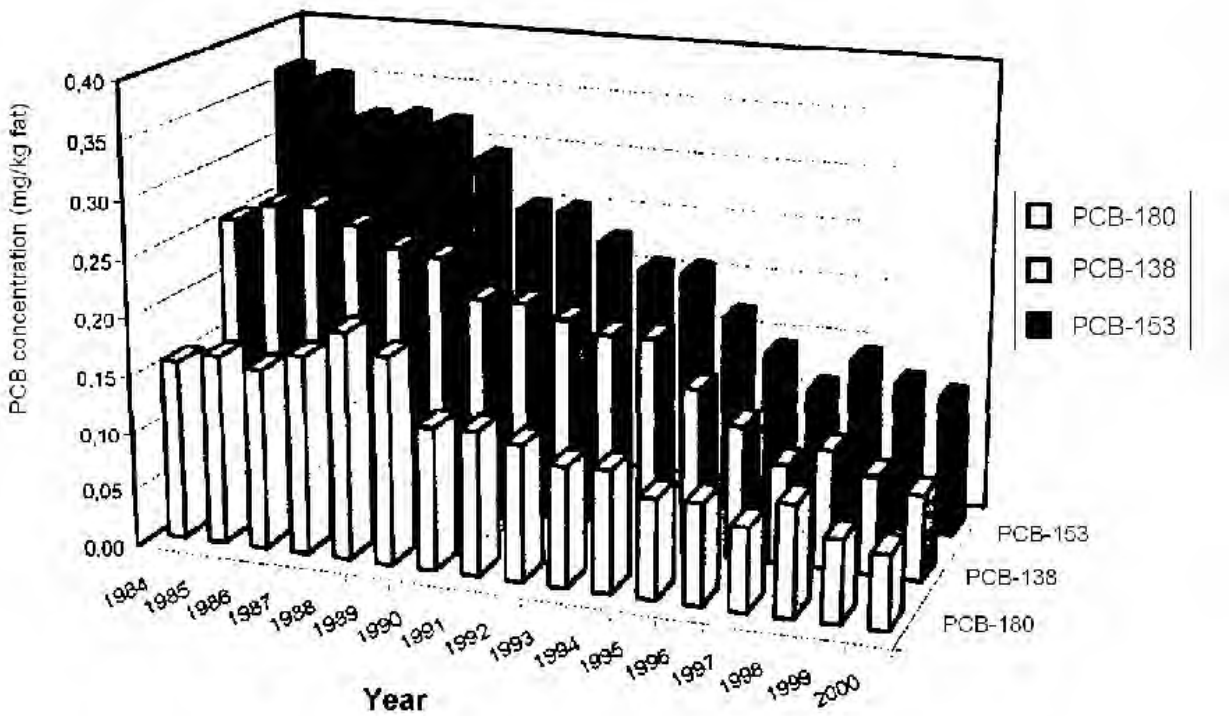
In Europe, concentrations of DL-PCBs (on a TEQ basis) and PCB indicators in human milk are considerably higher than in other regions of the world, a legacy from past exposures. For the sum of PCB_6, the median of 115.3 ng/g lipid is between 3.8 times and 10.7 times higher than in other regions of the world, and maximum concentrations are up to 14.9 times higher (IPCS, 2003). However, a WHO survey identified a decrease in WHO-TEQ PCDD/PCDF and PCB concentrations in human milk over the last decade (Van Leeuwen *et al.*, 2002). It was assumed that this decrease was the result of the ban of PCB use in open systems, and the strict regulations on the use of PCBs and on their disposal in closed systems.

Norén & Meironyté (referenced in IPCS, 2003) reported a steady decrease (from 910 to 324 ng/g lipid) in total PCB concentrations in the breast milk of Swedish women between 1967 and 1997. A declining trend could be observed for the sum of the PCB_6 in Germany, and mean values for the congeners PCB-138, PCB-153 and PCB-180 were approximately 60–70% lower in 2000 than in 1984 (Fürst, 2001; Fig. 1.8). An approximately 74% decrease in DL-PCB concentrations during the last decade was reported in Italy (Di Domenico & Turrio Baldassarri, 1990; Weiss *et al.*, 2003; Abballe *et al.*, 2008). Analyses of milk samples from the Czech Republic also revealed a decline in median concentrations between 1994 and 2000, the strongest decrease being observed between 1994 and 1997 (Cerná *et al.*, 2008). Nevertheless, it should be noted that concentrations in areas with heavy contamination did not show a significant decline in exposure over the past 10 years.

(iv) Asia

In Japan, a time-trend study showed that average PCB concentrations in human milk increased from 1.3 ng/g in 1972 to a peak of 1.5 ng/g in 1974, and then decreased by about 13% in 1998 (Environment Agency of Japan, 1999). In contrast, daily intake of PCBs from breast milk was estimated to decrease from 22.3 μg/g to 0.31 μg/g during this same period. [This trend reflects a change in PCB concentrations in food, due to both a decrease in contamination and more dependence on imported foods, which were less

Fig. 1.8 PCB concentrations in human milk in Germany, 1984–2000



From Fürst (2001)
PCB, polychlorinated biphenyl

contaminated than domestic foods (IPCS, 2003), and is consistent with the observed decline in PCB concentrations in the environment and in human tissues.]

In China, a national investigation of individuals in 12 provinces representing approximately 50% of the total Chinese population reported PCDD/PCDF-TEQ and total-TEQ in human milk from rural areas to be lower than those from urban areas (Li *et al.*, 2009). Positive correlations were found between total-TEQ in human milk and the consumption of aquatic food and meat.

PCB levels in breast milk samples from women in Asia are summarized in Table 1.29 and Table 1.30.

(c) Adipose tissue

(i) North America

Lordo *et al.* (1996) reported PCB concentrations (sum of tetra- to octochlorobiphenyls) in pooled adipose tissue to be 672 ng/g in 1986, compared with 407 ng/g in 1982, and 508 ng/g in 1984. Stellman *et al.* (1998) reported a total PCB concentration of 267 ng/g in breast adipose tissue of healthy women from Long Island, New York. An approximation of Aroclor 1260 [summed concentrations of PCB-138 and PCB-153 multiplied by 5.2] measured in breast adipose tissue, was reported to be 870 ng/g (Aronson *et al.*, 2000). Muscat *et al.* (2003) measured PCB concentrations (sum of 14 congeners) in breast adipose

tissue in women without metastatic breast cancer to be 361 ± 235.9 ng/g and 395.4 ± 279.3 ng/g, in women who did not have recurrence and women who did have recurrence, respectively.

(ii) Europe

The results of a study conducted in 1993–94 suggested that concentrations of PCBs in adipose tissue are the best indicator of long-term exposure or of total body burden of PCBs, compared with human milk or blood (Kocan *et al.*, 1994).

PCB concentrations in adipose tissue of the general population in industrialized countries vary very widely, ranging from < 1000 to 5000 ng/g fat (Falandysz *et al.*, 1994; Holoubek *et al.*, 1995, 2001b). In a comparative study in Europe (Van Bavel *et al.*, 2003), PCB concentrations in the population in Sweden were one third (mean, 661.9 ng/g fat; range, 247.2–1651.2 ng/g fat; Σ37 PCBs) of those in the Hungarian samples.

(iii) South and Central America

Breast adipose tissue in 76 women from an agricultural region of north-eastern Argentina contained eight PCBs at very low levels (only 1.3% above detection limits), but high levels of *p,p*-dichlorodiphenyldichloroethane (DDE) and other pesticides (Muñoz-de-Toro *et al.*, 2006).

The sum of four PCB congeners in children from Nicaragua was 530 ng/g lipid weight (2.0 ng/g wet weight) in those living and working near a waste-disposal site and eating fish from contaminated Lake Managua, 230 ng/g lipid weight (0.9 ng/g wet weight) in those living nearby but not working at the waste site and not eating fish, and 160 ng/g lipid weight (0.6 ng/g wet weight) in those living at a distance from the waste site and not eating fish (Cuadra *et al.*, 2006).

(iv) Asia

PCB concentrations in adipose tissue were reported from Yusho and Yucheng patients (see Table 1.30 and Table 1.31).

(v) Adipose versus serum measurements

Arrebola *et al.* (2012a, b) measured concentrations of three PCB congeners in serum and adipose tissue in adults from Bolivia. PCB-138 had median concentrations of 0.2 ng/mL in serum [33.7 ng/g lipid] and 84 ng/g in adipose tissue [105 ng/g lipid]. The median values for PCB-153 was 0.3 ng/mL in serum [59.0 ng/g lipid], and 52.7 ng/g in adipose tissue [65.8 ng/g lipid]. PCB-180 had median values of 0.1 ng/mL in serum [26.7 ng/g lipid] and 32.8 ng/g in adipose tissue [41.0 ng/g lipid].

(d) Umbilical cord blood, placenta, and fetal tissue

(i) North America

Stewart *et al.* (2000) reported cord blood PCB concentrations from women living along Lake Ontario and eating contaminated fish. The average cord blood PCB concentration was 0.525 ng/g wet weight [25th percentile, 0.174 ng/g wet weight; 75th percentile, 1.11 ng/g wet weight]. In plasma from umbilical cord in Inuit women from northern Canada, the geometric mean for the sum of 14 PCB congeners was 279.9 ng/g lipid (range, 70.8–1420.1 ng/g lipid) (Muckle *et al.* 2001). Dallaire *et al.* (2003) reported changes in concentrations in umbilical cord blood in this population over time, and found a 7.9% annual decrease between 1994 and 2000. Choi *et al.* (2006) measured 51 congeners in cord blood from women living near a PCB-contaminated site in Massachusetts, and reported a geometric mean of 0.40 ng/g (range, 0.068–18.14), with no consistent relationship with residential distance from the waste site. Consumption of meat and local dairy products (but not fish) were associated with higher cord blood PCB concentrations.

In women from New York state, Schecter *et al.* (1998) reported the concentration of three dioxin-like PCBs to be 18.2 pg/g lipid in placenta, giving a TEQ of 1.05. The concentrations of 14 single PCB congeners in plasma from Inuit

women from Nunavik and southern Quebec were highly correlated with those in placenta (Pearson's $r = 0.77–0.97$; $P < 0.001$), and concentrations in Inuit women were on average four times higher than in women from southern Quebec (Pereg *et al.*, 2002). Doucet *et al.* (2009) analysed placenta from Canadian women having elective abortions in 1998–2006 and reported annual average total PCB concentrations ranging from 7 to 70 ng/g lipid, with no clear time trend.

(ii) Europe

Koopman-Esseboom *et al.* (1994) used the concentrations of four congeners (PCB-118, PCB-138, PCB-153, and PCB-180), as measured in umbilical cord blood and in breast milk, as indicators of exposure of the developing fetus and breastfed infant. For these congeners, the correlation coefficients between maternal plasma, cord plasma and human milk were highly significant.

Soechitram *et al.* (2004) analysed PCBs (PCB-118, PCB-138, PCB-146, PCB-153, PCB-156, PCB-180) and hydroxylated metabolites of PCBs (PCB-107, PCB-136, PCB-146, PCB-153, PCB-172, PCB-187) in samples of maternal plasma and corresponding cord blood in the Netherlands. The calculated ratio for cord versus maternal blood was 1.28 ± 0.56 for PCBs and 2.11 ± 1.33 for hydroxylated PCBs, expressed per gram of lipid. A significant correlation between the respective maternal and cord concentrations for both PCBs and hydroxylated PCBs was found. The results indicated that approximately 50% and 30% of hydroxylated PCBs and PCBs, respectively, was transferred across the placenta to the fetus.

(e) Hair

(i) North America

Altshul *et al.* (2004) reported median PCB concentrations (sum of 57 congeners) in hair of 2640 ng/g fat (range, 1180–3620 ng/g fat) in a population of students in Boston, USA. Washing hair with shampoo decreased concentrations of PCBs by 25–33% on average, and up to 62% for less chlorinated congeners. [The Working Group considered that the analytical method was reliable and reproducible.] The concentrations of PCBs in hair were higher than in serum. Correlation between concentrations in hair and blood was moderate for the more persistent PCB congeners, with no or little correlation for the other congeners.

(ii) Europe

Covaci *et al.* (2002b) assessed PCB exposure in hair samples from Greece, Romania, and Belgium. Mean PCB concentrations in samples from Belgium were up to 14 ng/g hair, while concentrations in samples from Greece were about three times lower. Similar ratios of PCB-153 over total PCBs were found for all three countries.

(iii) Asia

One study measured PCB concentrations in the hair of pregnant women in various cities in the Islamic Republic of Iran (see Table 1.29).

1.5 Occupational exposure to PCBs

In 1978, an estimated 12 000 persons in the USA were exposed occupationally to PCBs (Lloyd *et al.*, 1976; NIOSH, 1977). Since the previous IARC evaluations of PCBs (IARC, 1978, 1987), occupational exposures to PCBs have changed, since most industrial countries have banned or partially banned their use. Nevertheless, the earlier references cited previously have been incorporated in the present monograph.

Earlier occupational exposures to PCBs occurred during PCB manufacture, capacitor and transformer manufacture and repair, production of carbonless copy paper, and accidental releases from these processes. More recent occupational exposures to PCB usually occur through PCB emissions via waste incineration, fires, and waste recycling.

1.5.1 PCB manufacture

The few available studies of occupational exposure among PCB-manufacturing workers have been performed in France, Italy, Japan, Poland and the USA. Workers' exposures during PCB manufacture have been mentioned since 1936 (Jones & Alden, 1936); air PCB concentrations ranged from 26 to 163 μg/m³. Evidence of extensive exposures was available from two larger clinical studies in Slovakia in which workers' blood concentrations were measured at 1160–9600 ng/g lipid (n = 242) (Langer *et al.*, 1997), and 4905–6540 ng/g lipid (n = 240) (Langer *et al.*, 2002). These workers had been employed at the plant for at least 5 years, but no information was given regarding the type of activities that they had performed.

1.5.2 Capacitor manufacture

Before PCBs were banned, capacitor manufacturers filled (impregnated) casings with wound paper and foil/plastic with the PCB-containing oil before the top was fastened (crimped, sealed, soldered). PCB exposure (probably via the dermal route) occurred during filling: the capacitors were either flood-filled or manually filled, resulting in spills and worker exposures. The brand of PCB oil used differed geographically (Aroclors were used in the USA, Pyralene/Phenochlor in Sweden and Italy) and temporally (the percentage chlorination was reduced, e.g there was a switch from Aroclor 1254, with 54% chlorination, to Aroclor 1242, with 42% chlorination.

Other chemical exposures in capacitor manufacturing were possible, such as from other impregnation oils (e.g. mineral oils), degreasing agents such as trichloroethylene (Brown & Jones, 1981; Bertazzi *et al.*, 1987), dibenzofurans (Gustavsson *et al.*, 1986), chlorinated naphthalenes, lead solder, epoxies, and methyl ethyl ketone (MEK) (Mallin *et al.*, 2004; Persky *et al.*, 2012). Ageing capacitors can from time to time explode [due to the physical stress of metal ageing], thus further exposing workers.

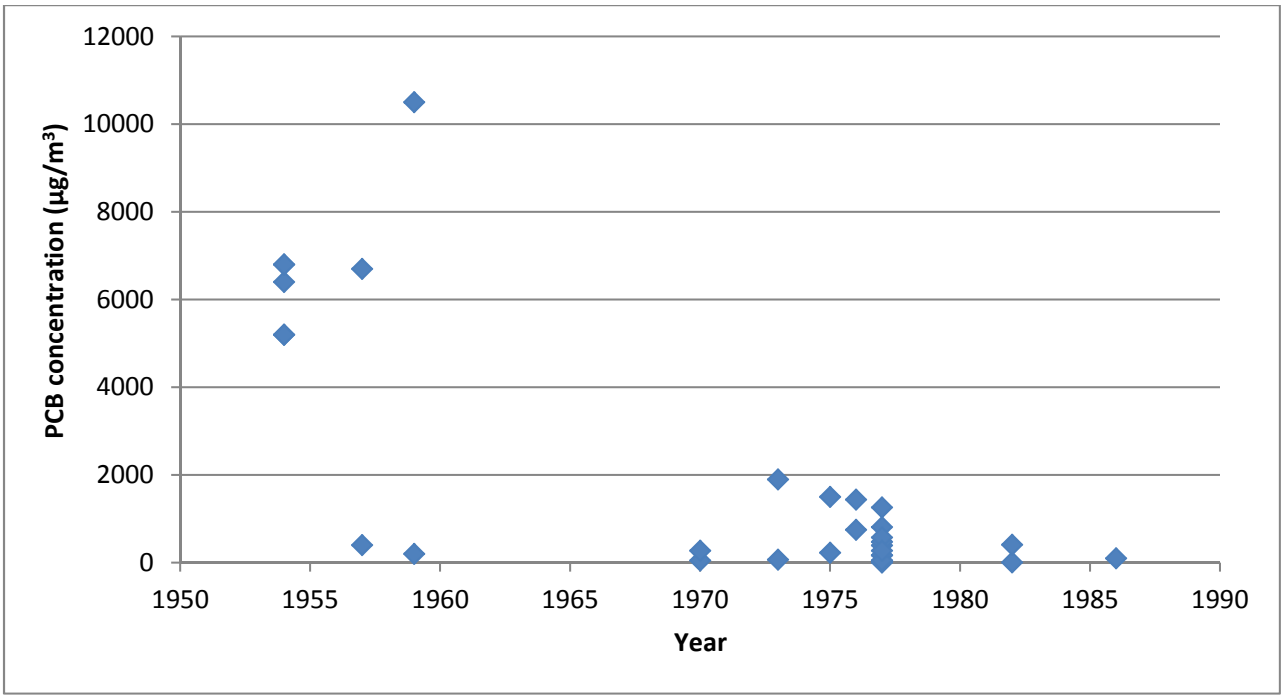
Fig. 1.9 shows ranges of air PCB concentrations in capacitor-manufacturing sites (Ouw *et al.*, 1976; Brown & Jones, 1981; Bertazzi *et al.*, 1982; Fischbein *et al.*, 1982; Lawton *et al.*, 1985; Gustavsson *et al.*, 1986). The earlier concentrations (measured in the 1950s–1960s) were highest (Bertazzi *et al.*, 1982), and decreased in later years.

In the 1950s, maximum PCB concentrations in workroom air in several plants in the USA (Massachusetts) were reported to be 200–10 500 μg/m³ (Elkins, 1959). No details on the number of plants surveyed, nor the number of samples collected, or the work performed in the plants were given, but four different jobs were surveyed: for impregnating with PCBs, average air concentrations ranged from 200 to 5800 μg/m³; for soldering, 800 μg/m³; mixing oil, 600 μg/m³, and regulator filling, 100 μg/m³. No toxic effects were noted at these concentrations; however, it was noted that air PCB concentrations of > 10 000 μg/m³ were "unbearably irritating." This is contrary to a report in a Japanese capacitor-manufacturing plant where a dermatitis outbreak occurred when air PCB concentrations reached 100 μg/m³ (Meigs *et al.*, 1954). Air PCB concentrations between 1953 and 1957 in a Japanese capacitor-manufacturing factory ranged from 400 to 6700 μg/m³ (NIEHS, 1976).

Ouw *et al.* (1976) reported that workers in the electrical industry in Australia were exposed to Aroclor 1242 at air concentrations of 320–2220 μg/m³, with a mean of 1270 μg/m³; and were found to have PCB blood concentrations of approximately 0.4 g/kg bw. Contact with PCBs was primarily via the skin.

Brown & Jones (1981) measured air concentrations of Aroclor 1016 in two plants in the USA (New York and Massachusetts) plants in 1977. The time-weighted averages (TWA) were different for the two plants, with air concentrations at the New York plant being lower than at the Massachusetts

Fig. 1.9 Air PCB concentrations in capacitor manufacturing plants (µg/m³) by year



Compiled by the Working Group using data from Ouw *et al.* (1976), Brown & Jones (1981), Bertazzi *et al.* (1982), Fischbein *et al.* (1982), Lawton *et al.*(1985) and Gustavsson *et al.*(1986)
PCB, polychlorinated biphenyl

plant. For the New York plant, PCB concentrations in personal air samples ranged from 24 to 393 µg/m³ (n = 28), and in area air samples from 3 to 476 µg/m³ (n = 19). For the Massachusetts plant, PCB concentrations in personal air samples ranged from 170 to 1260 µg/m³ (n = 29), and in area air samples from 50 to 810 µg/m³ (n = 25). Air PCB concentrations (TWA) were extremely high during capacitor impregnation (New York: 160 µg/m³, Massachusetts: 850 µg/m³), degreasing (Massachusetts; 1260 µg/m³), and sealing/soldering (New York: 393 µg/m³, Massachusetts: 720 and 1060 µg/m³). Capacitors that failed were sent for repair where they were re-opened and manually drained. Repair workers' PCB exposures were measured as 298 µg/m³ (recovery), and 50 µg/m³ (repair) in the New York plant. [These workers would also have had extensive dermal exposures, which were not assessed.]

Eight studies have reported PCB concentrations in workers' blood in Australia, Finland, Italy, Germany, and the USA (Karppanen & Kolho, 1972; Ouw *et al.*, 1976; Maroni *et al.*, 1981a; Bertazzi *et al.*, 1982; Acquavella *et al.*, 1986; Wolff *et al.*, 1992; Kannan *et al.*, 1994; Seegal *et al.*, 2011; Persky *et al.*, 2012). The reporting of PCB blood concentrations was not uniform, which hindered comparison across studies.

Karppanen & Kolho (1972) compared blood PCB concentrations in workers in a capacitor factory in Finland where Aroclor 1242 had been used as the impregnating fluid: the groups comprised laboratory workers handling PCBs (n = 6), impregnation workers (n = 11) employed for 4 years, and a control group (n = 9) that had never been professionally exposed to PCBs. Blood PCB concentrations were approximately 50 times greater in impregnation workers (0.07–1.9 µg/g)

than in the control group (0.003–0.012 μg/g), and were also higher in laboratory workers (0.036–0.062 μg/g) than in the controls. The pattern of PCB congeners in the exposed workers differed markedly from that of the PCBs actually used. More highly chlorinated PCBs persisted in the blood, while the less chlorinated PCBs contained in Aroclor 1242 had been eliminated from the body. [Consequently, the total PCB intake must have been higher than that reflected by the levels detected in blood.]

Total serum PCB concentrations have been reported to be 18.2 ppb (Acquavella *et al.*, 1986) in a clinical survey among 205 workers at a capacitor-manufacturing plant in the USA. This mean value represented workers (n = 205) with (39%) and without (61%) potential for PCB exposure in their jobs. [The Working Group noted that PCB concentrations were not reported separately for workers with and without occupational PCB exposure.] Log serum PCB concentrations were found to be significantly correlated with duration of employment, age, cumulative occupational exposure, and fish and wine consumption, as confirmed by multiple linear regression.

In a study of mortality in Italy (Bertazzi *et al.*, 1982), workers in the autoclave room were exposed to air PCB concentrations of 5200–6800 μg/m^3 in 1954 (n = 3), and 48–275 μg/m^3 in 1977 (n = 9). Eighteen workplace surface-wipe samples showed extensive PCB contamination (0.2–159 μg/cm^2), as did nine hand-wipe samples (0.3–9.2 μg/cm^2). Workers' serum PCB concentrations were reported by type of PCBs: for highly chlorinated PCBs (54% chlorination) (n = 67), the mean was 230.5 ppb (SD, 174.5), while for less chlorinated PCBs (42% chlorination) (n = 67) the mean was 114.1 ppb (SD, 79.6). In a later study (Bertazzi *et al.*, 1987), the corresponding values were 202.8 ppb (SD, 111.7; n = 37) and 42.9 ppb (SD, 34.7; n = 37), respectively.

Wolff *et al.* (1992) studied PCB blood concentrations in capacitor workers in 1976 and 1979 in the USA. For the first sampling year, the mean concentration of the less chlorinated PCBs (di-, tri-, and tetrachlorobiphenyls) was 55 ng/mL (range, 6–2257 ng/mL), and for the latter year was 41 ng/mL (range, 6–350 ng/mL). Mean concentrations of highly chlorinated PCBs were 10 ng/mL (range, 1–308 ng/mL) in 1976, and 13 ng/mL (range, 2–350 ng/mL) in 1979. These capacitor workers (n = 60) were also surveyed by the National Institute for Occupational Health and Safety in 1977 (NIOSH, 1977), when the following blood PCB concentrations were reported as follows: less chlorinated PCBs (quantified as Aroclor 1242), 2–3300 ppb (ng/mL), and more highly chlorinated PCBs (quantified as Aroclor 1254), 5–250 ng/mL.

About 30 years later (in 2003–2006), Seegal *et al.* (2011) measured blood concentrations of individual PCB congeners in some of these former capacitor workers, and found that concentrations had dropped statistically significantly: mean concentration of less chlorinated PCBs (PCBs 28, 56, 66, 74, 99, 101) was 2.84 ng/g or 0.45 μg/g lipid in men, and 2.29 ng/g or 0.34 μg/g in women; mean concentration of highly chlorinated PCBs (PCBs 105, 118, 138, 146, 153, 156, 167, 170, 172, 174, 177, 178, 180, 183, 187, 199, 203) was 4.09 ng/g or 0.65 μg/g lipid in men, and 3.21 ng/g or 0.47 μg/g lipid in women; and total PCB concentration was 7.47 ng/g or 1.19 μg/g lipid in men, and 5.81 ng/g or 0.86 μg/g lipid in women.

Maroni *et al.* (1981a) carried out a study in two Italian electrical-capacitor manufacturing plants using PCBs as a dielectric fluid. Plant A produced electric capacitors filled with a mixture of mineral oils and PCBs. PCBs with 54% chlorination were used from 1949 to 1965, and subsequently replaced with Pyralene 3010 with 42% chlorination. The power-capacitor casings were filled with PCBs in autoclaves, and were manually removed when cooled from 70 °C to 40 °C before they were welded, tested, and finished externally. Electric "filters" (small capacitor systems used in electrical household appliances)

were impregnated with PCBs. Plant B performed short-circuit testing of high-power capacitors filled with Apirolio, a PCB mixture with 42% chlorination. Stress-testing the capacitors often included explosions. Airborne PCBs were mainly trichlorobiphenyls and concentrations ranged from 48 μg/m^3 (filter operations) to 275 μg/m^3 (power-capacitor manufacturing). Surface-wipe samples showed both tri- and pentachlorobiphenyl mixtures, with the highest amounts being found on the capacitor basket rolling carrier: trichlorobiphenyls, 127 mg; and pentachlorobiphenyls, 15 mg. Plant A employed 67 workers (40 women and 27 men): 48 were currently employed in the capacitor-manufacturing departments, 16 had been employed there for at least 6 months before the beginning of the study, and 3 had always been employed in other non-manufacturing departments without direct exposure to PCBs. PCB recovery from the palms of the hands of power-capacitor workers (plant A) showed total PCB (tri- and pentachlorinated biphenyls) skin-surface concentrations to be 4–28 μg/cm^2. Mean (± SD) blood PCB concentrations differed between current (377 ± 190 μg/kg) and past exposed workers (292 ± 161 μg/kg); workers with occasional exposure had the lowest mean total PCB exposures (110 ± 31 μg/kg). Blood PCB concentrations by job performed were highest for welders (1259 μg/kg), followed by impregnation workers (556 ± 337 μg/kg), assembly of capacitors (406 ± 173 μg/kg), and finally assembly of filters (246 ± 130 μg/kg). The blood PCB concentrations were not correlated with duration of exposure, but with the percentage ratio of hours per year spent with direct exposure to PCBs. Plant B included 13 workers (all men) exposed to PCBs during handling of the capacitors contaminated with Apirolio, dispersed from explosions sometimes caused by stress-testing. Blood PCB concentrations in currently exposed workers in plant B (200 ± 146 μg/kg) were between occasionally exposed (110 ± 31 μg/kg) and past exposed workers (292 ± 161 μg/kg) in plant A. Although the PCB mixture used in both plants had a chlorine content of 42%, the workers differed in their ratio of penta- to trichlorobiphenyls; plant A workers had higher concentrations of pentachlorobiphenyls than of trichlorobiphenyls, while the reverse was true in plant B workers. This difference was attributed to the heavy past exposure to highly chlorinated PCBs used until 1965 in plant A. Workers with abnormal liver findings (n = 16) had twice the concentrations of tri- (215 ± 95 μg/kg) and pentachlorobiphenyls (308 ± 306 μg/kg) compared with workers (n = 64) without abnormal liver findings (tri- and pentachlorobiphenyl concentrations were 92 ± 64 and 176 ± 108 μg/kg, respectively) (Maroni *et al.*, 1981b). Duration of exposure did not explain this observed difference.

One German capacitor-manufacturing worker was reported to have a blood PCB-169 concentration of 11 ng/g (Kannan *et al.*, 1994).

After a capacitor explosion at a Finnish paper mill, workers' (n = 15) blood PCB concentrations were 3.5–48.3 μg/L (Luotamo *et al.*, 1984). [These levels were much lower than during capacitor manufacturing itself.]

In a recent cross-sectional study, Persky *et al.* (2012) reported blood PCB concentrations separately for diseased (having diabetes) and non-diseased (without diabetes) workers. In diseased workers, the concentrations were: DL-PCBs, 2.5 ng/g; NDL-PCBs, 17.0 ng/g; estrogenic PCBs [PCB-52, 99, 101, 110, 153], 3.6 ng/g; anti-estrogenic PCBs [PCB-105, PCB-156], 3.6 ng/g; and PCB-74, 4.9; PCB-99, 1.0 ng/g; PCB-118, 1.4 ng/g; PCB-138, 2.5 ng/g; PCB-146, 0.4 ng/g; PCB-153, 2.8 ng/g; PCB-156, 0.6 ng/g; PCB-170, 0.7 ng/g; PCB-180, 1.1 ng/g; PCB-187, 0.3 ng/g; PCB-194, 0.2 ng/g; PCB-201, 0.2 ng/g; PCB-203, 0.2 ng/g; and PCB-206, 0.1 ng/g. In non-diseased workers, the concentrations were: DL-PCBs, 0.4 ng/g; NDL-PCBs, 4.3 ng/g; estrogenic PCBs, 1.0 ng/g; anti-estrogenic PCBs, 0.1 ng/g; PCB-74, ng/g; 0.8, PCB-99; 0.3 ng/g; PCB-118, 0.2 ng/g; PCB-138, 0.6 ng/g; PCB-146, 0.1 ng/g; PCB-153,

0.8 ng/g; PCB-156, 0.1 ng/g; PCB-170, 0.2 ng/g; PCB-180, 0.4 ng/g; PCB-187, 0.1 ng/g; PCB-194, 0.1 ng/g; PCB-201, 0.1 ng/g; PCB-203, 0.1 ng/g; and PCB-206, 0.04 ng/g.

1.5.3 Transformer manufacture and repair

Transformer manufacture was very similar to capacitor manufacture. Transformers were filled with PCBs, but the impregnation fluid was usually diluted with other chlorinated solvents (e.g. trichlorobenzene; Greenland *et al.*, 1994), and sold under different names such as Askarel (Inerteen), Pyranol, Chlophen, Apirolio, and Derol (Kerns, 1975; Lees *et al.*, 1987; Emmett *et al.*, 1988; Kalina *et al.*, 1991; Greenland *et al.*, 1994; Yassi *et al.*, 1994; Altenkirch *et al.*, 1996; Loomis *et al.*, 1997; Caironi *et al.*, 2005).

Although air concentrations from transformer manufacture were not available, two studies reported air PCB concentrations during transformer repair in two different USA plants (Lees *et al.*, 1987; Emmett *et al.*, 1988). Work activities were sampling and testing transformer fluids for dielectric properties, topping up transformers when oil levels were low, clean-up of any spills or leaks, repair of transformers by drainage of transformer oil to replace parts, and periodic filtering of the transformer oil to upgrade its dielectric properties. Ranges of air PCB concentrations for several job tasks were reported: repair and clean-up (n = 3), 43.1–60.0 μg/m^3 and TWA, 16.7–24.0 μg/m^3; clean-up of PCB leakage (n = 3), 0.1–3.1 μg/m^3 and TWA, 0.01–0.4 μg/m^3; and secondary oil leak repair and clean-up (n = 15), 2.1–17.1 and TWA, 0.7–12.4 μg/m^3 (Emmett *et al.*, 1988). Other job tasks for which concentrations were reported were draining and pumping transformer oil (n = 9), 1.1 μg/m^3; transformer repair (n = 15), 1.2 μg/m^3; network repair (n = 6), 0.5 μg/m^3; topping-up transformer oil (n = 3), 0.5 μg/m^3; explosion spill clean-up (n = 16), 1.7 μg/m^3; and filtering transformer oil (n = 6), 6.1 μg/m^3 (Lees *et al.*, 1987). Transformer-repair activities included handling transformer parts that were wet with transformer fluid without protective gloves, resulting in extensive dermal exposure. In one case, a maintenance transformer worker involved in cleaning up transformer fluid spills daily had a plasma PCB concentration of 250 μg/L (Tröster *et al.*, 1991). [This value is comparable to highly exposed capacitor-manufacturing workers.]

1.5.4 Waste incineration of PCB materials

Ten studies from seven countries (USA, Germany, Spain, Japan, the Republic of Korea, Belgium, and Poland) reported PCB exposures during waste incineration of PCB materials (Colucci *et al.*, 1973; Angerer *et al.*, 1992; Wrbitzky *et al.*, 1995; Gonzalez *et al.*, 2000; Kitamura *et al.*, 2000; Domingo *et al.*, 2001; Raemdonck *et al.*, 2006; Mari *et al.*, 2009; Park *et al.*, 2009). The PCB congeners frequently reported in this industry were PCB-28, PCB-138, PCB-153, and PCB-180. The distribution of PCB congeners in plasma depended on the type of waste material, the furnace (age and type), and the workers' activities. During burning of waste in a waste-incinerating plant, heat from combustion gases is recuperated in a cauldron to produce electricity. PCBs are, together with dioxins, produced by synthesis from organic substances and chorine during this and subsequent cooling-down processes. PCBs (with dioxins) precipitate onto particulate matter (fly ash) and are trapped in the filter (Raemdonck *et al.*, 2006).

Exposed refuse workers (n = 37) in the USA had a median plasma PCB concentration of 2.6 ppb (maximum, 14.1 ppb) (Colucci *et al.*, 1973). [No methods were reported.] Hazardous-waste workers (n = 53) in Germany had a mean plasma PCB concentration of 6.33 μg/L calculated as the sum of PCB congeners PCB-138 (1.86 μg/L) + PCB-153 (2.83 μg/L) + PCB-180 (1.65 μg/L), which was not significantly different

from controls (6.22 µg/L) in the same study (Angerer *et al.*, 1992).

Another study in Germany (Wrbitzky *et al.*, 1995) reported mean plasma PCB concentrations in waste-incineration workers (total PCBs, 3.10 µg/L; range, 1.59–6.89 µg/L) that were approximately half those in the previously described study (Angerer *et al.*, 1992). The total PCBs were the sum of the same PCB congeners as previously reported: PCB-138, 0.95 µg/L (range, 0.49–2.60 µg/L); PCB-153, 1.38 µg/L (range, 0.97–3.10 µg/L); PCB-180, 0.79 µg/L (range, 0.32–1.63 µg/L). Concentrations of PCB-28, PCB-52, and PCB-101 were below the limit of detection (< 0.2 µg/L). These workers operated the incinerator, control panels, electronics, waste gas and transfer stations, and maintained and cleaned boilers and furnaces. Workers employed in the central laboratory, incoming control and sampling, chemical-sorting station, waste-water purification, and mechanical workshop among other periphery jobs had blood PCB concentrations similar to those of workers in management. Concentrations in exposed workers were: total PCBs, 2.82 µg/L; range, 1.21–7.03 µg/L, and this was the sum of PCB-138 (0.87 µg/L; range, 0.24–2.35 µg/L), PCB-153 (1.22 µg/L; range, 0.27–2.83 µg/L), and PCB-180 (0.72 µg/L; range, 0.32–3.48 µg/L). Concentrations in workers in management were: total PCBs, 3.19 µg/L (1.59–7.53 µg/L); PCB-138, 0.98 µg/L (0.49–1.98 µg/L); PCB-153, 1.42 µg/L (0.67–3.37 µg/L); PCB-180, 0.80 µg/L (0.43–2.18 µg/L). [Of the six PCB congeners analysed, only these three were detected.]

Waste-incinerator workers in a plant in Spain were reported to have mean total PCB concentrations of 1.47 µg/L: as in the German study, this was the sum of congeners PCB-138 (0.36 µg/L) + PCB-153 (0.49 µg/L) + PCB-180 (0.57 µg/L) (Gonzalez *et al.*, 2000). Congeners PCB-28 and PCB-52 were not detected, and the concentration of PCB-101 was very low (0.02 µg/L). In another study in Spain, congener-specific concentrations were reported as means (and geometric means): PCB-28, 18.5 (12.9) µg/kg lipid; PCB-52, 10.4 (7.5) µg/kg lipid; PCB-101, 9.0 (7.1) µg/kg lipid; PCB-138, 151 (129) µg/kg lipid; PCB-153, 213 (182) µg/kg lipid; and PCB-180, 209 (158) µg/kg lipid (Domingo *et al.*, 2001). [Although the distribution of congeners differed between the two studies, the PCB concentrations could not be directly compared as the latter values were lipid-adjusted.]

Kitamura *et al.* (2000) reported blood PCB concentrations in Japanese waste workers ($n = 94$) for other PCB congeners: mean (median) PCB-77, 148.59 (149.07) pg/g lipid; PCB-126, 131.81 (98.60) pg/g lipid; and PCB-169, 104.55 (90.45) pg/g lipid. [None of these congeners were measured in the other studies.]

Workers ($n = 15$) employed as operators for incinerators, boiler-maintenance, furnace maintenance, control panel, and waste-gas washing had a mean concentration of total PCBs of 115.7 µg/kg lipid (PCB-28, 0.7 µg/kg lipid; PCB-138, 17.5 µg/kg lipid; PCB-153, 45.5 µg/kg lipid; PCB-180, 52 µg/kg lipid) (Mari *et al.*, 2009). The sum of congeners PCB-138 + PCB-153 + PCB-180 in this study resulted in a total concentration of 115 µg/kg lipid, which was five times lower than that reported in the workers in Spain (573 µg/kg lipid) (Domingo *et al.*, 2001).

In 26 waste-incineration workers from the Republic of Korea, Park *et al.* (2009) found a mean concentration of total PCBs of 214.93 ng/g lipid (median, 161.13 ng/g lipid), of which hexachloro- and heptachloro-congeners accounted for 70% (congeners measured, PCB-77, PCB-81, PCB-105, PCB-114, PCB-118, PCB-123, PCB-126, PCB-156, PCB-157, PCB-167, PCB-169, and PCB-189). [Co-exposures to dioxins, furans, and other combustible products found in fly-ash are common for waste-incineration workers.] The waste-incinerator workers did not have statistically significantly higher PCB concentrations than control subjects ($n = 7$) (mean PCB concentration, 19.13 ng/g lipid; median, 94.63 ng/g lipid).

1.5.5 Electronic-waste recycling and scrap-metal dealers

One study reported PCB exposures of workers in e-waste recycling in China (Wen *et al.*, 2008). However, they did not report air or serum PCB concentrations, but PCB concentrations in hair samples collected from 94 workers. The PCB concentration range was 55.4–7200 ng/g.

In 17 scrap-metal dealers in two plants in the USA, mean serum PCB concentrations were 7.5 ppb (range, 1–65.3 ppb) (Malkin, 1995). Serum PCB concentrations were significantly related to eating lunch outside the lunchroom [suggesting hand-to-mouth contact as a source of exposure]. The gas-chromatography peak pattern resembled that of Aroclor 1260. [Both waste recycling and scrap handling result in coexposures to dioxins and metals.]

1.5.6 Locomotive-repair workers

Locomotive-repair workers (n = 120) in the USA were found to have elevated serum concentrations of PCBs, which was attributable to exposure to transformer fluids (Pyranol, Inerteen, Aroclor) (Chase *et al.*, 1982). Workers were divided into three exposure groups: "exposed" workers who had frequent opportunity for direct contact with PCB-containing transformer fluids; "nominally exposed" workers in the facility did not have opportunity for contact with PCBs; and "non-exposed" workers whose work environment did not involve any PCB fluids. Workers' plasma PCB concentrations were: exposed workers, 33.4 ppm (10–312 ppm); nominally exposed workers, 14.2 ppm (10–30 ppm); and non-exposed workers, 12.0 ppm (10–27 ppm).

1.5.7 Miscellaneous use of PCB oil

PCBs can be emitted by several other sources, including light ballasts and microscopic immersion oil, which contains 30–45% PCBs. Fluorescent light ballasts emit PCBs during burnout (IARC, 1978) and air concentrations depend on the distance from the source. Since the previous *IARC Monograph* on PCBs (IARC, 1978), no new studies regarding PCB exposures during work with carbonless copy paper, microscopic immersion oil, or after a fluorescent light ballast burnout have been published.

One study reported a PCB air measurement from a carbonless copy paper stockroom of 0.07 mg/m^3 (Tatsukawa, 1976). Hasegawa *et al.* (1973) reported that blood PCB concentrations in workers in carbonless paper producing plants (0.01–0.02 µg/g) 2 years after exposure were 10% those found during the period when the PCBs were used. No air or biological monitoring data have been published to assess the extent of PCB exposures during the use of microscope oil (Bennett & Albro, 1973). Four and a half hours after burn-out of a ballast, the concentration of PCBs was the highest (166 µg/m^3) 1 m below the burned-out ballast, while the lowest concentration (12 µg/m^3) was found at a distance of 4.5 m from the fixture (Staiff *et al.*, 1974).

In 1958–1978 in Canada, areas around transformers mounted outdoors were treated with phenoxy herbicides (2,4-D and 2,4,5-D) to reduce foliage (Hay & Tarrel, 1997). To increase adherence of the herbicides to the plant leaves, herbicide sprayers (n = 225) would mix 4 pounds [1.8 kg] of phenoxy herbicide with 10 gallons [37.9 L] of used transformer fluid and 90 gallons [340.7 L] of water before spraying. PCB exposures were not measured during this operation.

Use of Aroclor 1254 was reported in a petrochemical plant in the USA during the 1950s, where 31 men had been "heavily exposed" (Bahn *et al.*, 1976). No information regarding how PCB was used was given [but could have been PCBs used as fluids for hydraulic and heat-transfer systems]. No air or blood concentrations of PCBs were reported.

United States navy vessels built between 1946 and 1977 commonly contained PCBs in insulation material, electrical cable, and ventilation

gaskets (Still *et al.*, 2003). In nuclear submarines, PCBs were also used in soundproofing material, missile-launch tubes, electrical cables, banding and sheet rubber, heat-resistant paints, hull coatings, and electrical transformers. Activities associated with PCB exposure during dismantling of these vessels were transformer clean-up and removal; cutting/crushing of PCB-contaminated steel, steel-shot blasting of PCB-contaminated surfaces, chiselling/hand-chipping of PCB-contaminated surfaces, and shoveling/sweeping of PCB-contaminated debris. Surface-wipe sampling showed PCB amounts ranging from non-detects to 11 000 µg/100 cm^2. [Information for PCB exposure in the military is scarce.]

Cumulative lifetime exposure to PCBs among Mohawk men at Akwesasne (a Native American community of more than 10 000 persons located along the St Lawrence River in New York, Ontario, and Quebec) who had been occupationally exposed to PCBs was positively associated with serum total PCB concentration ($P = 0.03$) (other non-occupational sources such as fish consumption and living close to hazardous waste sites discussed in the article are not referenced here). The congener profile was most similar to that of Aroclor 1248, the commercial mixture used at local industrial facilities (Fitzgerald *et al.*, 2007) as a hydraulic fluid in a foundry's die-casting machines from 1959 to 1974, and as a component in aluminium-processing heat-transfer equipment. The occupational exposure of Mohawk men was independently assessed by two occupational hygienists as the probability of exposure to PCBs for all jobs of more than 6 months duration with the following qualitative ratings: (1) definitely not exposed; (2) possibly exposed; (3) probably exposed; and (4) definitely exposed. These ratings were assigned weights of zero, 0.25, 0.5, and 1.0, respectively. The weights for each job were then multiplied by duration of employment in that job, and the results were summed over all jobs to estimate cumulative lifetime occupational exposure to PCBs for each man. [The Working Group noted that this population was also exposed environmentally (see Section 1.4.1(a)).]

A qualitative PCB exposure assessment among welders in Sri Lanka was performed recently (Lankatilake *et al.*, 2012). PCB oil extracted from discarded transformers was widely used as coolant oil in small-scale welding facilities in Sri Lanka to facilitate heat transmission and thereby assist in the cooling process. Exposure to coolant oil occurs during replacement of the coolant and while repairing machinery. The amount of coolant oil used in a welding machine depends on the type of machine, but on average is about 5 L. During repairs, there is a high risk of exposure to PCBs in the transformer oil.

1.5.8 Occupations with exposure to PCB by-products

PCBs have also been reported as a by-product in an electric arc furnace steelmaking plant in the United Kingdom (Aries *et al.*, 2008). Air PCB concentrations in decreasing order by department were: melting shop, 586 pg/m^3 (range, 144–1313 pg/m^3); casting area, 187 pg/m^3 (range, 73–272 pg/m^3); control cabin, 99 pg/m^3 (range, 57–129 pg/m^3). The most prominent congeners were PCB-118 (100–500 pg/m^3), PCB-105 (10–80 pg/m^3), and PCB-77 (5–35 pg/m^3).

Using static high-volume samplers (0.2 m^3/min for 12 hours or 24 hours) in a basic oxygen steelmaking (BOS) and iron ore sintering plant, Jackson *et al.* (2012) calculated mean TEQ pg/m^3 for the by-products PCDD/F and PCBs. The BOS process involves the transfer, desulfurization, and refining of hot metal in a steel converter, and secondary steelmaking treatments. Sintering is a process for blending and fusing iron-ore fines, fluxes, coke, and recycled materials (grit and dusts from other processes). Air concentration ranges were: sinter plant, 0.19–3.72 TEQ pg/m^3 ($n = 12$); and BOS plant, 0.08–0.71 TEQ pg/m^3 ($n = 24$). In

all instances, concentrations of PCBs were much higher than of PCDD/Fs. PCB-126 contributed significantly to the total TEQ (5–20%).

PCBs have been reported as a by-product in penta- and trichlorophenol wood-preservation pesticide manufacturing with PCDFs and PCDDs (Hryhorczuk *et al.*, 1998; Collins *et al.*, 2008). Serum PCB concentrations (sum of PCB-77, PCB-81, PCB-126, and PCB-169) were measured by the company in these workers (Collins *et al.*, 2008): for pentachlorophenol workers only (n = 26; period exposed, 1944–1980) 73.6 pg/g lipid; trichlorophenol workers only (n = 12; period exposed, 1954–1979): 75.9 pg/g lipid; pentachlorophenol and trichlorophenol workers (n = 14; period exposed, 1961–1980): 86.3 pg/g lipid; tradesmen (n = 10): 121.1 pg/g lipid. These PCB concentrations were not much different from those of a selected reference population (n = 36; 75.0 pg/g lipid).

1.5.9 Removal of PCB-containing sealants

PCB-containing sealants were used in building construction before PCBs were banned in that country. For example, sealant used in Sweden contained 4.7–8.1% Clophen A40 (Sundahl *et al.*, 1999). Air PCB concentrations of 10–120 µg/m^3 were reported after removal of the sealant by a variety of methods: cutting the elastic sealant with an oscillating knife; grinding the concrete with a mechanical machine; sawing the concrete with a mechanical saw; or cutting the concrete with a mechanical chisel. The removal methods were changed by equipping the tool with suction, which reduced air PCB concentrations to non-detects to 3.1 µg/m^3 (Kontsas *et al.*, 2004). Serum PCB concentrations in sealant-remover workers were 0.6–17.8 µg/L (mean, 3.9 µg/L; and median, 1.9 µg/L). For highly chlorinated PCBs, the mean was 3.5 µg/L (median, 1.6 µg/L), and for less chlorinated PCBs, the mean was 0.4 µg/L (median, 0.2 µg/L). Correlation between concentrations in air and serum was only noted for PCB-28 and PCB-52.

During sealant removal in Finland, total PCB concentration in dust samples was 0.026 mg/m^3 (Priha *et al.*, 2005). Congeners determined in the sealant were: PCB-28, 82 mg/kg; PCB-52, 3030 mg/kg; PCB-77, 37 mg/kg; PCB-101, 10 325 mg/kg; PCB-118, 6145 mg/kg; PCB-126, 42 mg/kg; PCB-138, 11 765 mg/kg; PCB-153, 11 185 mg/kg; PCB-169, 32 mg/kg; and PCB-180, 7254 mg/kg (Priha *et al.*, 2005).

Swedish construction workers removing PCB-containing sealants had serum PCB concentrations (sum of 19 congeners) of 575 mg/g lipid, while controls (construction workers not involved in PCB abatement work) had levels of 267 mg/g lipid (Seldén *et al.*, 2008; Wingfors *et al.*, 2006). Concentrations of PCB-180 were not significantly different between groups, while concentrations of many less chlorinated PCBs (especially PCB-66 and PCB-56/PCB-60, but also PCB-28, PCB-44, PCB-52, PCB-74, PCB-101, and PCB-105) were much higher in the exposed workers than in the controls.

1.5.10 People working in contaminated buildings

People working in contaminated buildings (office workers, teachers) are exposed to PCBs (Wiesner *et al.*, 2000); PCB concentrations have been surveyed in workers' air (Gabrio *et al.*, 2000; Schwenk *et al.*, 2002; Peper *et al.*, 2005; Schettgen *et al.*, 2012) and blood (Gabrio *et al.*, 2000; Schwenk *et al.*, 2002; Peper *et al.*, 2005; Herrick *et al.*, 2011; Schettgen *et al.*, 2012).

Mean indoor air concentrations of PCBs in three contaminated schools in Germany were reported to be between 77 and 10 125 ng/m^3; 90% of the total PCBs were either PCB-28 or PCB-52 (Gabrio *et al.*, 2000). These congeners were also reported to be found at high concentrations (> 4000 ng/m^3) in other studies in Germany (Schwenk *et al.*, 2002; Peper *et al.*, 2005; Schettgen *et al.*, 2012). The teachers (n = 96) working in the three contaminated buildings had mean

blood PCB-28 concentrations that differed by school (0.045 µg/L, 0.057 µg/L, and 0.098 µg/L, respectively), and that were significantly elevated compared with teachers (n = 55) not working in contaminated schools (range, not detected to 0.035 µg/L) (Gabrio *et al.*, 2000).

Median indoor air concentrations were measured over 2 years in schools in Germany for congeners PCB-28 (33 ng/m³), PCB-52 (293 ng/m³), and PCB-101 (66 ng/m³) (Liebl *et al.*, 2004). Concentrations of more highly chlorinated indicator congeners (PCB-153, PCB-138, and PCB-180) were all below 80 ng/m³. The median sum of indicator congeners was 2.04 µg/m³. Biomonitoring of teachers (n = 9) and cleaning personnel (n = 1) in schools in Germany showed that median blood PCB concentrations exceeded the German reference values after adjusting for age in 8 out of 10 workers for PCB-138, 7 out of 10 for PCB-153, and 8 out of 10 for PCB-180 (Neisel *et al.*, 1999).

In teachers in the USA, the relative contribution of lighter congeners (PCBs 6–74) (mean total serum PCB concentration, 1.86 ng/g; n = 18) was higher than in controls (Herrick *et al.*, 2011). This was also observed in other studies: mean concentration of PCB-28, 0.28 µg/L; PCB-101, 0.07 µg/L; PCB-138, 1.29 µg/L; PCB-153, 1.68 µg/L; and PCB-180, 1.14 µg/L in Peper *et al.*, (2005); median concentration of PCB-28, 0.087 µg/L; PCB-52, 0.024 µg/L; and PCB-101, 0.012 µg/L in Schettgen *et al.*, (2012); and mean concentration of PCB-28, 0.24 µg/L; PCB-52, 0.07 µg/L; PCB-101, 0.02 µg/L; PCB-153, 0.96 µg/L; PCB-138, 0.70 µg/L; and PCB-180, 0.62 µg/L in Schwenk *et al.*, (2002).

People working inside contaminated buildings other than schools may also be exposed to PCBs. In Germany, air PCB concentrations in contaminated commercial buildings were 1280 ng/m³ (PCB-28, 110 ng/m³; PCB-52, 125 ng/m³; PCB-101, 11 ng/m³; PCB-138, < 2 ng/m³; PCB-153, < 2 ng/m³; PCB-180, < 2 ng/m³) (Broding *et al.*, 2007). The PCB contamination originated from insulation material and elastic sealing compounds. Serum PCB concentrations were determined in 2002 for 583 persons who had worked between 1 and 40 years in the contaminated commercial building. The median serum total PCB concentration was 2.32 µg/L (PCB-28, 0.09 µg/L; PCB-52, 0.01 µg/L; PCB-138, 0.55 µg/L; PCB-153, 0.9 µg/L; and PCB-180, 0.7 µg/L). People not working in the contaminated building (n = 205) had significantly lower serum concentrations of PCB-28 and PCB-52 (0.023 µg/L and 0.004 µg/L, respectively) (Broding *et al.*, 2008).

1.5.11 Clean-up of hazardous waste

Occupational exposure to PCBs has also been measured in workers who perform clean-up of hazardous waste. After an explosion and fire of unlabelled chemical waste drums at the former site of Chemical Control Corporation in Elizabeth, New Jersey, USA, the mean air PCB concentration was 0.11 µg/m³ (n = 3) (Costello & King, 1982). In workers (n = 32) removing hazardous waste, including transformers, in the USA, plasma PCB mean concentration was 205 ng/g lipid (range, limit of detection to 527 ng/g lipid) (Horii *et al.*, 2010). Hexa and heptachlorinated biphenyls accounted for 60% of the PCB concentrations.

1.5.12 Firefighters and rescue workers

Firefighters and rescue workers have also been surveyed for PCB exposure in several recent studies, demonstrating a wide variability in serum PCB concentrations (Table 1.33; Kelly *et al.*, 2002; Schecter *et al.*, 2002; Dahlgren *et al.*, 2007; Chernyak *et al.*, 2009, 2012).

1.6 Exposure assessment of epidemiological studies

1.6.1 Studies of occupational exposure

Many epidemiological studies of occupational PCB exposure and cancer have been performed; the majority are among workers in capacitor-manufacture and transformer manufacture and repair. Duration of employment was used to assess exposure in most of these studies (Brown & Jones, 1981; Bertazzi *et al.*, 1982, 1987; Cammarano *et al.*, 1984; Brown, 1987; Nicholson & Selikoff, 1987; De Guire *et al.*, 1988; Taylor *et al.*, 1988; Liss, 1989; Petruska & Engelhard, 1991; Greenland *et al.*, 1994; Tynes *et al.*, 1994; Yassi *et al.*, 1994, 2003; Gustavsson *et al.*, 1986; Savitz & Loomis, 1995; Tironi *et al.*, 1996; Gustavsson & Hogstedt, 1997; Hay & Tarrel, 1997; Kimbrough *et al.*, 1999, 2003; Loomis *et al.*, 1997; Charles *et al.*, 2003; Mallin *et al.*, 2004; Caironi *et al.*, 2005; Prince *et al.*, 2006a, b; Ruder *et al.*, 2006; Ahrens *et al.*, 2007; Hopf *et al.*, 2009b, 2010, 2014; Silver *et al.*, 2009; Pesatori *et al.*, 2013). In the remaining studies, exposure to PCBs was assessed using a variety of approaches, including job-exposure matrices (JEM), development of worker's exposure zones, and measurement of serum PCB concentrations.

JEMs were used in several studies (Greenland *et al.*, 1994; Loomis *et al.*, 1997; Prince *et al.*, 2006a, b; Ruder *et al.*, 2006; Silver *et al.*, 2009).

Greenland *et al.* (1994) developed a JEM in a case–control study of cancer mortality at a transformer-assembly facility. Pyranol was used as the transformer oil from 1936 to 1976. Pyranol was composed of 50% PCBs (mainly hexachlorobiphenyls) and 50% trichlorobenzene, but the PCB content could vary from 45% to 80%. A combination of 1000 job titles in 50 departments in 100 buildings resulted in more than 5500 entries in the JEM. Each entry was rated for seven selected exposures from 1901 to 1984. A four-point categorical rating scale was used to rate the jobs. Former employees and experienced industrial hygienists rated each entry. For pyranol, benzene, and solvents, the analysis categories were: 0, no exposure; 1, indirect exposure, meaning that the chemical was found in the work area, but the worker did not perform tasks using it; 2, direct exposure. Cumulative exposures were calculated using these scores and individual job histories.

A cancer mortality study among electric-utility workers in five companies exposed to PCBs used job categories to estimate weekly exposures in hours for each job (Loomis *et al.*, 1997). PCBs were used in capacitors, transformers and switches. Capacitor fluids were 100% PCBs, while transformer fluids contained 70% PCBs and 30% chlorinated benzene solvents. Exposure assessments were performed by expert panels for each company. The panel members (industrial hygienists, safety personnel, managers, and long-term workers) recorded their individual exposure assessments for PCBs, and other exposures, which were later discussed to resolve differences. For each occupational category and decade, the frequency in times per week and duration in hours of exposure to insulating fluids during the average working week was indicated. This was used to construct company and calendar time-specific JEMs Industrial hygiene surveys of the plants were used to interpret the panel's exposure assessment. Each occupational category (in total, 28) was classified according to workers' potential exposure to PCBs.

Three plant-specific semiquantitative JEMs were used in a study of cancer of the breast in former capacitor-manufacturing workers (women) in Indiana, Massachusetts, and New York, USA (Silver *et al.*, 2009). Two of these JEMs had been used previously in a mortality study (Prince *et al.*, 2006a, b) of former workers at the Indiana and Massachusetts plants, and one in a mortality study of former workers at the Indiana plant (Ruder *et al.*, 2006). Two of the three JEMs have been described in detail in separate publications (Hopf *et al.*, 2009b,

Table 1.33 Serum PCB concentrations in firefighters

Country	Population	Activity	PCB congeners measured	Mean serum PCB concentration	Reference
USA	Firefighters (n = 58)	Extinguishing a transformer fire	NA	2.96 ppb (range, 1.9–9.6 ppb)	Kelly *et al.* (2002)
	Rescue workers (n = 7)	Working during the collapse of the World Trade Center, New York, September 2001	Non-*ortho* PCBs	43–328 pg/g lipid	Dahlgren *et al.* (2007)
			Mono-*ortho* PCBs	19–404 ng/g lipid	
			ΣDL-PCBs[a]	19–405 ng/g lipid	
Russian Federation	Firefighters, symptomatic (n = 8)	Participated in extinguishing a fire at a cable-manufacturing plant (no SCBA)	ΣDL-PCBs[a]	198.6 pg/g lipid	Chernyak *et al.* (2009, 2012), Schecter *et al.* (2002)
	Firefighters, asymptomatic (n = 5)	Participated in extinguishing a fire at a cable-manufacturing plant (no SCBA)	ΣDL-PCBs[a]	198.9 pg/g lipid	
	Firefighters (n = 7)	Other fires	ΣDL-PCBs[a]	231.7 pg/g lipid	
			Congener 77, 126, 169	Symptomatic firefighters > than the other groups	Schecter *et al.* (2002)

[a] DL-PCBs, dioxin-like PCBs, i.e. PCBs 77, 81, 105, 114, 118, 123, 126, 156, 157, 167, 169, 189

NA, not available; PCB, polychlorinated biphenyl; SCBA, self-contained breathing apparatus

2010). Exposure determinants or factors that influenced PCB exposures for each plant were assessed for all jobs listed in the work histories. Jobs with similar rating of the exposure determinants were grouped into exposure categories. Each job-exposure category, exposure intensity (high, medium, low, background) and frequency (continuous, intermittent) were qualitatively rated separately for inhalation and dermal exposure. The plant-specific JEMs used available air PCB concentrations (the same as in Sinks *et al.* (1992) for the Bloomington plant) to assign inhalation weightings. The product of intensity and frequency (fraction of day exposed) was calculated for each job-exposure category. Finally, the JEM was modified for eras with different conditions of PCB exposure (change in Aroclor use, ventilation-system improvements, lay-out changes etc).

[These historical reconstructions are better than using duration of employment alone in the epidemiological studies, since duration does not distinguish between jobs with higher or lower potential for PCB exposure. Most of these retrospective studies involved manufacturing plants that used limited amounts of other chemicals, or at least when other chemicals were used, these jobs were often indicated and could be excluded from the epidemiological analysis. Creating cohorts of today's working environment would include a very diverse industry with multitude of job activities, including an array of different chemicals. Therefore it would be difficult to draw definitive statements on the causations of a possible observed mortality excesses.]

In their retrospective study of mortality, Sinks *et al.* (1992) developed workplace exposure zones to classify worker exposure. The capacitor-manufacturing plant studied was divided into five zones of exposure by drawing consecutive circles (radius, approximately 69 m) centred upon the heaviest source of PCB exposure. The production area was thus divided into three zones by proximity to PCB source. Two other zones were

defined: maintenance and office workers. Air sampling was conducted in these five zones, and means were assigned as the weight (1–5) of PCB exposure for the zone.

Serum PCB concentrations were used in one case–control study (Laden *et al.*, 2001b), and in a recent cross-sectional study (Persky *et al.*, 2012) (see Section 1.5.2).

1.6.2 Studies of environmental exposure

Cohort studies of environmental exposure have used many approaches to assess exposure to PCBs. Exposure approaches include interview, questionnaires, cumulative PCB exposure, dietary intake of fatty fish, PCB concentrations in biological media such as blood, adipose tissue, and breast milk, and in the environment such as carpet dust, or any combinations of these. Biological measures of body burden have been used extensively (see Table 1.34).

1.7 Regulations and guidelines

1.7.1 Global

For Parties to the Stockholm Convention on Persistent Organic Pollutants (POPs) (UNEP, 2001), presently 179 Member States, the production of PCBs is totally prohibited, although the presence of PCBs in equipment is allowed to continue until 2025. The environmentally sound management of waste containing or contaminated with PCBs at a content above 0.005% must be achieved by 2028.

Annex I of the Basel Convention on the Transboundary Movements of Hazardous Wastes and Their Disposal (UNEP, 2011) defines a category of hazardous waste specific to PCBs: "Y10 waste substances and articles containing or contaminated with PCBs and/or polychlorinated terphenyls (PCTs) and/or polybrominated biphenyls (PBBs)." Additionally, Annex VIII defines as "hazardous" any electrical waste containing or contaminated with PCBs at a concentration greater than 50 mg/kg. The Basel Convention is legally binding for 179 countries (status in 2013).

The Codex Alimentarius Commission, recognizing the importance of prevention of human exposure through source-directed measures (i.e. strict control of industrial and agricultural processes that may generate and release PCDDs, PCDFs, and PCBs), adopted the Code of Practice Concerning Source Directed Measures to Reduce Contamination of Food with Chemicals (CAC/RCP 49–2001) (Codex Alimentarius, 2001) and the Code of Practice for the Prevention and Reduction of Dioxin and Dioxin-like PCB Contamination in Foods and Feeds (CAC/RCP 62–2006) (Codex Alimentarius, 2006). No limits in foodstuffs were included, but management options were recommended.

(a) Provisional tolerable monthly intake

In 2002, the Joint Food and Agriculture Organization of the United Nations (FAO)/WHO Expert Committee on Food Additives (JECFA) established a provisional tolerable intake of 70 pg/kg bw per month for PCDDs, PCDFs, and DL-PCBs expressed as TEFs, based on reproductive end-points (JEFCA, 2002). The value was expressed "per month" to reflect that exposure is cumulative and chronic rather than acute.

(b) Drinking-water

No water quality guidelines have been set for these substances because of their low solubility in water.

(c) Air

Air quality guidelines for PCBs have not been established, because exposure by direct inhalation generally constitutes only a small proportion of total exposure, in the order of 1–2% of the daily intake from food. Although this air concentration is only a minor contributor to direct human exposure, it is a major contributor to contamination of the food-chain (WHO, 2000).

Table 1.34 Common measures of exposure to PCBs and design of the exposure assessment in epidemiological studies in non-occupational settings

Exposure measure	Exposure assessment	Examples of exposure categories reported
Cumulative PCB exposure	Regular jobs held	• Job-exposure schemes • Industry classifications • Potential exposure to PCBs as assessed by an occupational hygienist
Dietary intake of fatty fish containing PCBs	Standardized questionnaires or interviews	• Number of fish meals per day
High-level dietary intake of contaminated rice oil (mass poisoning)	Admission to hospital	• Area of residence
Environmental PCB concentrations	PCB concentrations in carpet dust PCBs in soil	• Amount of PCBs in dust • Amount of PCBs in soil
PCB concentrations in biological samples	Serum PCB concentration, non-lipid adjusted	• Sum of PCB congeners • High or low PCB body burden: 'high' exposure (higher than the median based on the control group) vs. 'low' exposure (lower than the median based on the control group)
	Serum PCB concentration, lipid adjusted	• Sum of PCB congeners measured • Single PCB congeners • Potentially estrogenic PCBs (PCB-44, PCB-54) and PCB-101, PCB-187 • Potentially anti-estrogenic, immunologic, dioxin-like, non-*ortho* substitution, mono-*ortho* substitution, moderately persistent (PCB-66, PCB-77, PCB-105, PCB-118, PCB-126) • Immunotoxic PCBs (PCB-66, PCB-74, PCB-105, PCB-118, PCB-138, PCB-153, PCB-156, PCB-167, PCB-180) • Di-*ortho* substitution, limited DL-PCBs and persistent PCBs (PCB-128, PCB-138, PCB-170) • Biologically persistent inducers of CYP1A and CYP2B • Environmentally relevant PCBs (PCB-195, PCB-206, PCB-209) • Neurotoxic PCBs (PCB-18, PCB-28) • Non-dioxin-like PCBs (PCB-74, PCB-99, PCB-118, PCBs 138–158, PCB-146) • Sum of DL-PCBs (PCB-105, PCB-118, PCB-156) • Sum of NDL-PCBs (PCB-28, PCB-99, PCB-138, PCB-153, PCB-170, PCB-183, PCB-187) • *BRCA1* inhibiting PCBs (PCB-101, PCB-138) • Pseudo-estrogen PCBs (PCB-28, PCB-52, PCB-153) • Phenobarbital inducers (PCB-101, PCB-153, PCB-180, PCB-194) • Most-represented congeners (PCB-118, PCB-138, PCB-153, PCB-180)
	Plasma PCB concentration	Sum of the four most prevalent PCB congeners (PCB-118, PCB-153, PCB-138, PCB-180)
	Adipose tissue PCB concentrations	Sum of 18 PCBs Sum of dioxin-like PCBs (PCB-77, PCB-126, PCB-169)
PCB concentrations in biological samples (cont.)	Tumour tissue PCB concentrations	Sum of PCB congeners (PCB-28, PCB-31, PCB-49, PCB-52, PCB-101, PCB-105, PCB-118, PCB-138, PCB-153, PCB-170, PCB-180), measured at the time of diagnosis

DL-PCB, dioxin-like polychlorinated biphenyl; NDL-PCB, non-dioxin-like polychlorinated biphenyl

1.7.2 Environmental regulations

(a) European Union and Member States

The Member States of the European Union have taken actions to eliminate the production, use, and release of PCBs since 1985. In 2004, to implement the Stockholm Convention on POPs, by regulation EC/850/2004 (EU 850/2004), the production, placing on the market, and use of PCBs were prohibited. Low POPs concentration limits were adopted through Council Regulation (EC) No. 1195/2006 (EU 1195/2006) amending Annex IV to Regulation (EC) No 850/2004. Within the European Union of 26 Member States, several measures have been adopted to reduce the presence of PCDDs, PCDDs, PCDFs, and PCBs in the environment, in food and in feed. These include:

- Commission Regulation (EC) No. 1883/2006 of 19 December 2006 laid down methods of sampling and analysis for the official control of levels of dioxins and DL-PCBs in certain foodstuffs;
- Commission Recommendation 2006/88/EC of 6 February 2006 concerning the reduction of the presence of dioxins, furans and PCBs in feedingstuffs and foodstuffs;
- Commission Recommendation 2006/794/EC of 16 November 2006 on the monitoring of background levels of dioxins, DL-PCBs and NDL-PCBs in foodstuffs.
- The most recent Commission Regulation (EU) No. 1259/2011 amended Regulation EU 1881/2006 as regards maximum levels for DL-PCBs and NDL-PCBs (EC, 2011a); it also changed the formerly used 1998 WHO TEFs to the scheme adopted in 2005 (referred to as WHO_{2005}-TEFs) (Van den Berg *et al.*, 2006) and includes maximum levels for NDL-PCBs in food.

  See Table 1.35

(b) North America

(i) USA

The United States Food and Drug Administration has established tolerance levels in various foods in an attempt to reduce human exposure to PCBs (FDA, 2013). [These limit values were set in 1971 and 1977, before any epidemiological and most experimental studies were conducted, and have not been revised since.] The temporary tolerance levels for PCB residues are as follows:

- 1.5 ppm in milk (fat basis);
- 1.5 ppm in manufactured dairy products (fat basis);
- 3 ppm in poultry (fat basis);
- 0.3 ppm in eggs;
- 0.2 ppm in finished animal feed for food-producing animals (except the following finished animal feeds: feed concentrates, feed supplements, and feed premixes);
- 2 ppm in animal feed components of animal origin, including fishmeal and other by-products of marine origin and in finished animal feed concentrates, supplements, and premixes intended for food-producing animals.
- 2 ppm in fish and shellfish (edible portion). The edible portion of fish excludes head, scales, viscera, and inedible bones;
- 0.2 ppm in infant and junior foods;
- 10 ppm in paper food-packaging material intended for or used with human food, finished animal feed and any components intended for animal feeds. The tolerance does not apply to paper food-packaging material separated from the food therein by a functional barrier that is impermeable to migration of PCB.

The United States Environmental Protection Agency (EPA) has set a maximum contaminant level for PCBs of 0.0005 mg/L (500 ppt) in drinking-water. The EPA requires that spills

Table 1.35 Maximum permitted levels for dioxin-like compounds and indicator PCBs in the European Food and Feed regulation

Foodstuffs	Maximum permitted levels[a]		
	Sum of PCDDs, PCDFs, DL-PCBs[b] (pg WHO_{2005}-TEQ per g fat)	DL-PCBs[b] (pg WHO_{2005}-TEQ per g fat)	Sum of PCB_6[c] (ng/g fat)
Meat and meat products (excluding edible offal) of the following animals):			
Bovine animals and sheep	4.0	1.75	40
Poultry	3.0	0.75	40
Pigs	1.25	0.5	40
Liver of terrestrial animals and derived products thereof	10.0		40
Muscle meat of fish and fishery products and products thereof (with the exemption of wild caught eel and wild-caught fresh water fish, with the exception of *diadromous* fish species caught in fresh water, fish liver and derived products, and marine oils)[a]	6.5 pg/g ww	2.5 pg/g ww	75 ng/g ww
Muscle meat of wild caught fresh water fish, with the exception of *diadromous* fish species caught in fresh water, and products thereof[d]	6.5 pg/g ww		125 ng/g ww
Muscle meat of wild caught eel (*Anguilla anguilla*) and products thereof	10.0 pg/g ww		300 ng/g ww
Fish liver and derived products thereof with the exception of marine oils referred to above	20.0 pg/g ww		200 ng/g ww
Marine oils (fish body oil, fish liver oil and oils of other marine organisms intended for human consumption)	6.0		200
Raw milk and dairy products, including butter fat	5.5	2.0	40
Hen eggs and egg products	5.0	1.75	40
Fat of the following animals:			
Bovine animals and sheep	4.0		40
Poultry	3.0		40
Pigs	1.25		40
Mixed animal fats	2.5	0.75	40
Vegetable oils and fats	1.25		40
Foods for infants and young children	0.2 pg/g ww		1.0 ng/g ww
Fruits, vegetables and cereals		0.1 pg/g ww	

[a] The maximum level expressed on fat is not applicable for foods containing < 2% fat (the maximum level expressed on product basis for foods containing < 2% fat = maximum level expressed on fat for that food × 0.02).

[b] The Commission Recommendation 2011/516/EU (EC, 2011b) replaces regulation 2006/88/EC and sets separate action levels for PCDD/PCDF (expressed as WHO_{2005}-TEQ) and DL-PCB (expressed as WHO_{2005}-TEQ).

[c] PCB_6 comprises PCB-28, PCB-52, PCB-101, PCB-138, PCB-153, and PCB-180

[d] The maximum level for crustaceans applies to muscle meat from appendages and abdomen. In the case of crabs and crab-like crustaceans (*Brachyura* and *Anomura*) it applies to muscle meat from appendages.

DL-PCB, dioxin-like polychlorinated biphenyl; PCDD, polychlorinated dibenzodioxins; PCDF, polychlorinated dibenzofurans; TEQ, toxic equivalent; ww, wet weight

Adapted from EC (2011a) and EC (2011b)

or accidental releases into the environment of 1 pound (0.45 kg) or more of PCBs be reported to the EPA (ATSDR, 1996).

(ii) Canada

The import, manufacture, and sale (for re-use) of PCBs were made illegal in Canada in 1977. Release of PCBs to the environment was made illegal in 1985. However, use of PCB-containing equipment is allowed until the end of its service life. The storage of PCBs has been regulated since 1988. Export has been regulated since 1997. These provisions are maintained in the Chlorobiphenyls Regulations, under the Canadian Environmental Protection Act, 1999 (CEPA, 2011).

The regulation of waste is consistent with the Basel Convention's "Technical guidelines for the environmentally sound management of wastes consisting of, containing, or contaminated with persistent organic pollutants" (Basel Convention, 2007, 2015).

(c) Australia and New Zealand

(i) Australia

The Industrial Chemicals (Notification and Assessment) Act 1989 was amended to give effect to the Stockholm Convention (NICNAS, 1989).

The National Strategy for The Management of Scheduled Waste was endorsed by the Australian and New Zealand Environment and Conservation Council in 2003 (ANZECC, 2003) and provides for the safe management and disposal of organochlorine pesticides, PCBs and hexachlorobenzene. The PCB Management Plan provides treatment provisions for different types of PCB waste including liquid residues and discharges, gaseous emissions, solid residues and disposal (Australian Government, 2006, 2007).

(ii) New Zealand

The Hazardous Substances and New Organisms (HSNO) Act 1996 (as amended by the HSNO [Stockholm Convention] Act Amendment 2003), prohibits the production, use and import of the chemicals listed in Annex A of the Convention, including PCBs. Exempted use of PCBs as per the Toxic Substances Regulations 1983 is permitted, but subject to phase-out no later than December 2016. The HSNO Act 1996 is administered by The New Zealand Environment Risk Management Authority (ERMA) by: assessing new chemicals, pesticides or industrial chemicals currently in use that exhibit POP characteristics (Articles 3.3 and 3.4); permitting the appropriate use of POPs for laboratory-scale research or as a reference standard (Article 3.5); managing the existing exempted use and storage of PCBs (Article 3.6); prohibiting import, manufacture, or use of POPs (Article 3.1 and 3.2). The Imports and Exports (Restrictions) Act 1988, via the Imports and Exports (Restrictions) Prohibition Order (No. 2) 2004, prohibits export of POPs (except as conditionally provided under Article 3.2). Import and export are regulated under The Imports and Exports (Restrictions) Act 1988.

(d) Asia

(i) China

China implements an import and export registration system, included under its Regulations on Environmental Management of Chemicals and the Import and Export of Toxic Chemicals of 1994. In 2005, PCBs were included in the List of Toxic Chemicals Strictly Prohibited from Import and Export, by No. 116 Notice on the List of Goods Prohibited from Import (the Sixth Group). The National Implementation Plan under the Stockholm Convention entered into force for China in 2004, and also applied to the Special Administrative Regions of Hong Kong and Macao (NIP China, 2007). This plan aims to prohibit and prevent the production and import of PCBs, and to achieve the environmentally sound management of currently used equipment containing PCBs. China used to produce PCBs, but production was stopped in the 1970s. The

plan called for establishing a system for the declaration, registration, and environmentally sound management of equipment in use containing PCBs by 2010. Identification of high-risk equipment currently in use across the country is to be achieved by 2015, with uses of PCBs eliminated by 2025.

Furthermore, China has also stipulated special administrative regulations and standards with regard to PCBs. The Notice on the Issues Concerning Prevention of Pollution Caused by Hazardous Polychlorinated Biphenyls was promulgated in 1979 to ban future imports of power equipment containing PCBs. The Notice on Enhancement of the Management over Waste Polychlorinated Biphenyl Power Capacitors was issued in 1990 to forbid trading and dismantling downstream capacitors containing PCBs. The Provisions on the Pollution Caused by Power Installations Containing Polychlorinated Biphenyls and Related Wastes of 1991 addresses the declaration, transfer, transport, import, treatment, disposal, sealing-up and storage of PCB wastes and other sources. The Control Standard on Polychlorinated Biphenyls for Wastes (GB13015–91) was implemented in 1991, in which the value of the control standard on PCBs wastes and the treatment methods for wastes containing PCBs are stipulated (NIP China, 2007).

(ii) Taiwan, China

Importation of PCBs was prohibited in 1980. The Environmental Protection Administration of Taiwan, China, banned the manufacture, sale, and use of PCBs in 1988. An extensive investigation of electrical devices in 1990–1991 indicated that more than 80 000 PCB-containing electrical devices were still in use, mainly capacitors and transformers. A full-scale ban on the use of PCBs, with the exception of experimental, research, and educational purposes, took effect in January 2001. This prohibited use of any electrical devices containing PCBs by the end of 2000, mandating immediate disposal at end of use of capacitors and transformers containing PCBs (Environmental Protection Administration, 1988). Furthermore, PCBs may not be detectable in effluents from business, sewage systems and building sewage-treatment facilities.

(iii) India

According to Schedule VI of the Hazardous Waste (Management, Handling and Transboundary Movement) Rules 2008, the import and export of hazardous wastes, substances and articles containing or consisting of or contaminated with PCBs are prohibited (Ministry of Environment and Forests, 2008).

(e) Africa

United Republic of Tanzania

The Industrial and Consumer Chemicals (Management and Control) Act of 2003 provides for the management and control of PCBs under the list of severely restricted/banned/eliminated chemicals in Schedule 8. The government of the United Republic of Tanzania issued an Environmental Management Act (Government of the United Republic of Tanzania, 2004) that specifically provides for the control and management of current and future POPs, requiring submission of an annual report on implementation.

1.7.3 Occupational exposure limits

(a) USA

The manufacture of PCBs ended in the USA in 1977. Standards for occupational exposures (permissible exposure limits; PELs) in the USA are set by the Occupational Safety and Health Administration (OSHA) (29CFR1910.1000 Table Z-1 Limits for air contaminants). The PELs are 8-hour TWAs unless otherwise noted, and are determined from breathing-zone air samples. The PELs established by OSHA are 1000 μg/m^3 for PCB mixtures containing 42% chlorine, and 500 μg/m^3 for PCB mixtures containing 54%

chlorine (set in 1971 and not revised after this time). Both standards encompass all physical forms of these compounds: aerosols, vapour, mist, sprays, and PCB-laden dust particles. OSHA recognizes that PCBs are absorbed through intact skin; therefore, routes for dermal and inhalation exposure should be evaluated by an industrial hygienist. The National Institute for Occupational Safety and Health (NIOSH) recommends a 10-hour TWA of 1 μg/m^3 based on minimum reliable detectable concentration and the potential carcinogenicity of PCBs. NIOSH also recommends that all workplace exposures be reduced to the lowest feasible level.

(b) Europe

The maximum allowable airborne concentrations for PCBs containing 42% and 54% chlorine in the Federal Republic of Germany [before reunification] were 1.0 and 0.5 mg/m^3, respectively; and in Sweden, 0.5 mg/m^3 (IARC, 1978).

2. CANCER IN HUMANS

2.1 Cohort studies of occupational exposure

Commercial mixtures of congeners of polychlorinated biphenyls (PCBs) were manufactured starting in the 1920s in Austria, France, Germany, Italy, Japan, Spain, Poland, the Russian Federation, the United Kingdom, and the USA. No published epidemiological studies of cancer among PCB-production workers were available to the Working Group.

2.1.1 Capacitor manufacture

Studies of cancer mortality and incidence among workers exposed to PCBs in the manufacture of capacitors have been conducted in Italy (Bertazzi *et al.*, 1982, 1987; Tironi *et al.*, 1996; Pesatori *et al.*, 2013), Sweden (Gustavsson *et al.*, 1986; Gustavsson & Hogstedt, 1997), and the USA (Brown & Jones, 1981; Brown, 1987; Sinks *et al.*, 1992; Kimbrough *et al.*, 1999, 2003; Mallin *et al.*, 2004; Prince *et al.*, 2006a, b; Ruder *et al.*, 2006; Silver *et al.*, 2009). The details of cohort studies among capacitor-manufacturing workers are presented in Table 2.1.

Bertazzi *et al.* (1982, 1987) studied 544 male and 1556 female former capacitor-production workers exposed between 1946 and 1980 at one capacitor-manufacturing plant in Monza, Italy. Cancer mortality until 1991 was non-statistically significantly increased among men (standardized mortality ratio, SMR, 1.1; 95% CI, 0.7–1.7; 20 deaths) and women (SMR, 1.2; 95% CI, 0.7–1.8; 19 deaths) (Tironi *et al.*, 1996). The most recent update also included 373 male and 97 female workers at a second plant that operated from 1950 to 1982 (Pesatori *et al.*, 2013). There was no excess overall cancer mortality; however, mortality due to cancers of the digestive tract, not otherwise specified, was statistically significantly increased (SMR, 2.5; 95% CI, 1.2–5.3; seven deaths). Deaths due to cancer of the brain (SMR, 1.8; 95% CI, 0.9–3.6; eight deaths) and lymphoma (SMR, 1.9; 95% CI, 1.0–3.3; twelve deaths) were in excess, especially for Hodgkin disease (SMR, 4.0; 95% CI, 1.3–12; three deaths) among women. Men were at increased risk of mortality from cancer of the biliary tract (SMR, 3.9; 95% CI, 1.5–10.4; four deaths) and cancer of the prostate (SMR, 1.7; [95% CI, 0.8–3.5]; seven deaths). [This cohort was notable for the high proportion of women.]

Gustavsson & Hogstedt (1997) studied cancer incidence and mortality until 1991 among 242 male capacitor-manufacturing workers employed for at least 6 months between 1965 and 1978 at a plant in Sweden. Individuals were classified as "high-exposed" if they had ever worked in the impregnation or repair departments. Cancer mortality was not significantly elevated among highly exposed workers (SMR, 1.9; 95% CI, 0.8–3.9; seven deaths). Two cases of cancer of the liver and bile duct were diagnosed (SMR, 6.7; 95% CI, 0.0–37 for highly exposed workers). Mortality from non-Hodgkin lymphoma (NHL) was increased among highly exposed workers based on one case (SMR, 9.1; 95% CI, 0.2–51).

Table 2.1 Cohort studies in capacitor-manufacturing workers

Reference, location, follow-up period	Total No. of subjects	Exposure assessment	Organ site (ICD code)	Exposure categories	Exposed cases	Relative risk (95% CI)	Covariates Comments
Tironi *et al.* (1996), Italy, 1954–1982	1556 women, 544 men	Employment, 1 wk, 1946–82	All cancers (140–209)	All women	19	SMR, 1.2 (0.7–1.8)	Update of cohort studied by Bertazzi *et al.* (1982, 1987)
				All men	20	SMR, 1.1 (0.7–1.7)	
			Digestive organs (150–159)	All women	2	SMR, 0.9 (0.1–3.3)	
				All men	10	SMR, 2.0 (0.9–3.6)	
			Lymphatic & haematopoietic (200–209)	All women	5	SMR, 1.4 (0.5–3.3)	
				All men	3	SMR, 2.0 (0.4–5.9)	
			Lymphoma (200–202)	Women	4	SMR, 1.8 (0.5–4.5)	
Pesatori *et al.* (2013), Italy, 1946–1978 (plant 1)	1551 women and 544 men (plant 1); 97 women and 373 men (plant 2)	Employment > 1 wk 1946–1978 (plant 1), all workers employed 1950–1982 (plant 2); PCBs used until 1980	All cancers	All workers	183	SMR, 1.0 (0.9–1.0)	
			Lymphoma (200–202)		12	SMR, 1.9 (1.1–1.3)	
			Digestive NOS (159)		7	SMR, 2.5 (1.2–5.3)	
			Brain		8	SMR, 1.8 (0.9–3.6)	
			Breast	All women	16	SMR, 0.8 (0.5–1.3)	
			Prostate	All men	7	SMR, 1.7 (0.8–3.5)	
Gustavsson & Hogstedt (1997); Gustavsson *et al.* (1986), Sweden, 1965–1991	242 men	Employed > 6 mo, 1965–1978; low, medium, or high exposure to PCBs	All cancers (140–209)	High-exposed	7	SMR, 1.9 (0.8–3.9)	Age, calendar period, country of origin
			Liver (155)	High-exposed	1	SMR, 6.7 (0.02–37)	
			Lung (162)	High-exposed	2	SMR, 2.2 (0.3–8.0)	
			Prostate (185)	High-exposed	1	SMR, 2.2 (0.1–12)	
			Lymphatic & haematopoietic (200–209)	High-exposed	1	SMR, 3.3 (0.1–19)	
			Lymphoma (200–202)	High-exposed	1	SMR, 9.1 (0.2–51)	

Table 2.1 (continued)

Reference, location, follow-up period	Total No. of subjects	Exposure assessment	Organ site (ICD code)	Exposure categories	Exposed cases	Relative risk (95% CI)	Covariates Comments
Mallin *et al.* (2004), Illinois, USA, 1944–2000	2885 white (25 non-white workers excluded)		All cancers (140–208)	All	347	[SMR, 1.1 (1.0–1.2)]	Sex, age, race, calendar period
			Stomach (151)	All	17	[SMR, 1.9 (1.1–3.1)]	Workers also exposed to trichloroethylene, 1,1,1-trichloroethane, lead solder, mineral oil, lacquer, paint thinner, epoxies, methyl ethyl ketone
			Intestine excluding rectum (152–153)	All	39	[SMR, 1.3 (0.9–1.7)]	
			Biliary passages, liver, & gallbladder (155–156)	All	14	[SMR, 2.4 (1.3–4.1)]	
			Thyroid (193)	Men	3	SMR, 15.2 (3.1–45)	No deaths from thyroid cancer among women
			Rectum (154)	All	7	[SMR, 1.1 (0.5–2.4)]	
			Prostate (185)	Men	9	SMR, 1.1 (0.5–2.0)	
			Breast (174–175)	Men	49	SMR, 1.2 (0.9–1.6)	
			NHL (200, 202)	Women:			No NHL deaths among those who worked 5–9 years. Data not reported for men
				Worked < 1 yr	7	SMR, 2.1 (0.8–4.3)	
				Worked 1–4 yr	4	SMR, 1.6 (0.4–4.1)	
				Worked ≥ 10 yr	2	SMR, 1.9 (0.2–6.8)	
			Oral cavity & pharyn (140–149)	Men only	3	SMR, 1.1 (0.2–3.3)	No deaths among women
Ruder *et al.* (2006), Indiana, USA, 1957–1998	3569	JEM based on department, job, tasks, monitored exposure levels, estimated cumulative exposure for each worker		*Cumulative exposure*			Sex, age, race, calendar period
			All cancers	Lowest tertile (< 11 000 unit-days)	56	SMR, 0.9 (0.7–1.2)	
				Middle tertile (11 000–89 999 unit days)	62	SMR, 0.9 (0.7–1.2)	
				Highest tertile (≥ 90 000 unit-days)	52	SMR, 0.8 (0.6–1.1)	*P* for trend = 0.48
			Melanoma	Lowest tertile	5	SMR, 3.7 (1.2–8.7)	
				Middle tertile	2	SMR, 1.5 (0.2–5.4)	
				Highest tertile	9	SMR, 2.4 (1.1–4.6)	*P* for trend = 0.72
			Brain	Lowest tertile	3	SMR, 1.4 (0.3–4.0)	
				Middle tertile	4	SMR, 1.8 (0.5–4.6)	
				Highest tertile	5	SMR, 2.7 (0.9–6.3)	*P* for trend = 0.016

Table 2.1 (continued)

Reference, location, follow-up period	Total No. of subjects	Exposure assessment	Organ site (ICD code)	Exposure categories	Exposed cases	Relative risk (95% CI)	Covariates Comments

[Findings based on this small cohort were difficult to interpret because of limited precision.]

A cohort of 2885 white workers employed between 1944 and 1977 at a capacitor-manufacturing facility in Illinois, USA, who were exposed to PCBs (1952–1977), chlorinated naphthalenes (1944–1981), and other chemicals, was followed until 2000 (Mallin *et al.*, 2004). Plant records were incomplete and short-term workers (less than 1 year employment) were least likely (83%) to have been traced. There was excess mortality from cancers of the stomach [SMR, 1.9; 95% CI, 1.1–3.1], liver and biliary tract [SMR, 2.4; 95% CI, 1.3–4.1] and breast [SMR, 1.2; 95% CI, 0.9–1.6]. Women with 5 or more years employment during the period of PCB use had significantly elevated mortality from cancers of the liver and biliary tract (SMR, 5.6; 95% CI, 1.5–14; four deaths) and intestine (SMR, 2.3; 95% CI, 1.0–4.3; nine deaths). Men had excess mortality from cancer of the thyroid (SMR, 15.2; 95% CI, 3.1–45; three deaths), while women had excess mortality from NHL, which was not related to the duration of employment (SMRs, 1.6–2.1). Data on NHL were not reported for men. [Exposure assessment was limited and workers were exposed to multiple chemicals, which hampered attribution of cancer outcomes to PCB exposure.]

The United States National Institute for Occupational Safety and Health (NIOSH) cohort (Ruder *et al.*, 2014) included 25 000 workers at facilities in three states, originally studied separately, in Indiana (Sinks *et al.*, 1992; Ruder *et al.*, 2006) and Massachusetts and New York (Brown & Jones, 1981; Brown, 1987; Prince *et al.*, 2006a, b), and combined for an analysis of cancer of the breast (Silver *et al.*, 2009). Separate job-exposure matrices were developed for each of the plants, based on department, job title, era, company records, information about job tasks, and sampling data (Nilsen *et al.*, 2004; Hopf *et al.*, 2009, 2010), with each worker receiving an estimated cumulative exposure score, so that cancer outcomes could be analysed by level of relative exposure.

Updating vital status until 1998 for the Indiana subcohort (which comprised 3569 workers exposed to PCBs between 1957 and 1977) confirmed the earlier findings of excess melanoma and cancer of the brain (Sinks *et al.*, 1992). Melanoma remained in excess (SMR, 2.4; 95% CI, 1.1–4.6), particularly in the lowest tertile of estimated cumulative exposure (SMR, 3.7; 95% CI, 1.2–8.7; five deaths). Mortality from cancer of the brain (SMR, 1.9; 95% CI, 1.0–3.3) increased with exposure, with a standardized mortality ratio of 2.7 (95% CI, 0.9–6.3; five deaths) in the highest quartile and a significant exposure–response trend in the standardized rate ratio (SRR) ($P = 0.02$). Among those having worked ≥ 90 days, both melanoma (SMR, 2.7; 95% CI, 1.1–5.2) and cancer of the brain (SMR, 2.1; 95% CI, 1.1–3.8) were elevated, especially for women (melanoma: SMR, 6.0; 95% CI, 1.2–17.5; three deaths; cancer of the brain: SMR, 2.9; 95% CI, 0.6–8.4; three deaths). The standardized mortality ratio for mortality from NHL was 1.2 (95% CI, 0.6–2.3) (Ruder *et al.*, 2006).

The original studies in the Massachusetts-New York subcohorts (Brown & Jones, 1981; Brown, 1987) included only 2567 workers considered to be highly exposed to PCBs during 1938–1977 (Massachusetts) or 1946–1977 (New York). The update until 1998 expanded the study population to include 14 458 workers with at least 90 days of potential exposure to PCBs (Prince *et al.*, 2006b). Cancer of the liver, leukaemia and aleukaemia [aplastic anaemia], and NHL were not in excess overall, but mortality from multiple myeloma was (SMR, 1.85; 95% CI, 1.23–2.67). In the New York subcohort, mortality from melanoma was elevated (SMR, 1.79; 95% CI, 0.98–3.0). Mortality from cancer of the stomach was elevated among men (SMR, 1.53; 95% CI, 0.98–2.28) and increased with cumulative exposure (trend, $P = 0.039$). Mortality from cancer of the prostate was not elevated overall (SMR, 1.0; 95% CI, 0.72–1.45),

but increased with cumulative exposure (trend, $P < 0.001$). Mortality from intestinal cancer was elevated among women (SMR, 1.31; 95% CI, 1.02–1.66), especially in categories with higher cumulative exposure, but did not show a clear trend.

[The NIOSH studies were originally reported in multiple, overlapping publications based on several plants, but were subsequently merged into a single cohort. The Working Group regarded the quality of the NIOSH studies as high, and noted that they represented considerable effort to enumerate, expand and update the cohorts and assess exposure using objective job-exposure matrices.]

In addition to the NIOSH studies, separate analyses were conducted independently for the New York plant (Kimbrough *et al.*, 1999, 2003). These studies, which used duration of employment and whether hourly or salaried as surrogates for exposure, reported on virtually the same workers as in the NIOSH New York subcohort (mortality until 1998, employed at least 90 days, 7075 workers versus the 6941 studied by NIOSH), but found no significant excess mortality for any cancers (Kimbrough *et al.*, 1999, 2003). [The Working Group noted that the analyses by Kimbrough included 134 more workers than did Prince et al. but was not able to determine the reason for the discrepancy. In addition, Kimbrough et al. presented results only in subgroups defined by sex and pay grade, limiting the power of the analyses.]

The NIOSH study of cancer of the breast (Silver *et al.*, 2009) included 5752 women employed for at least 1 year in any one of the three capacitor-manufacturing facilities studied previously by NIOSH. Exposure to PCBs was estimated semiquantitatively using job-exposure matrices and information about incident cancer of the breast, parity, age at first live birth, breast cancer in a first-degree female relative, hormone use, and smoking was used in analyses for 3952 women who completed questionnaires. Cancer registries and death certificates up to 1998 were used to identify 281 incident cases. The overall standardized incidence ratio (SIR) for cancer of the breast was 0.8 (95% CI, 0.7–0.9), with little effect of employment duration or cumulative exposure. However, for the 282 women of race identified by questionnaire as "other than white," there was a positive, statistically significant association with cumulative exposure, with a hazard ratio for cancer of the breast of 1.3 (95% CI, 1.1–1.6) per 1000 unit-years of estimated cumulative exposure, while no association was observed in "white" women.

2.1.2 Transformer manufacture and repair

Studies of cancer mortality and incidence among workers exposed to PCBs in the manufacture or repair of transformers have been conducted in Canada (Yassi *et al.*, 1994, 2003), Italy (Caironi *et al.*, 2005), and the USA (Greenland *et al.*, 1994; Table 2.2).

Cancer mortality among a subset of deceased former workers at a transformer-manufacturing plant in Massachusetts, USA, was evaluated for (ever having had) exposure to PCBs (Pyranol) (Greenland *et al.*, 1994). There were positive associations with cancer of the liver and biliary tract (odds ratio, OR, 2.4; 95% CI, 0.6–9.7) and lymphoma (OR, 3.3; 95% CI, 1.1–9.3). In an analysis adjusted for age at death, year of death, and year of hire, the adjusted odds ratio was 2.2 (95% CI, 0.8–6.5) for cancer of the liver and biliary tract and 1.5 (95% CI, 0.55–4.3) for lymphoma. [The Working Group noted that numbers of deaths by site associated with exposure to PCBs were not reported, and job histories were unavailable for 34% of the study population.]

Cancer incidence and mortality until 1995 were studied in a cohort of 2222 men working between 1946 and 1975 at a transformer-manufacturing plant in Manitoba, Canada, where PCBs (Askarels) were used from 1956 to fill large transformers (mineral oils were used in other

transformers) (Yassi *et al.*, 2003). The mortality study showed an increased risk of mortality for cancer of the digestive tract, particularly cancers of the stomach and pancreas, among workers in the transformer-assembly department. The incidence study included ten cases of malignant melanoma in the full cohort (SIR, 2.2; 95% CI, 1.1–4.0). Increased risk of cancers of the gall bladder and pancreas was also observed among all workers, and an excess of cancer of the pancreas was reported among workers in the transformer-assembly department (SIR, 7.2; 95% CI, 1.5–21.1) (Yassi *et al.*, 2003). [The Working Group noted that the authors did not assess individual exposure to PCBs, which makes it difficult to attribute effects specifically to PCBs.]

In a study in Bergamo, Italy, among 471 workers who built transformers between 1950 and 1988, using PCBs until 1980 and mineral oils thereafter, and who repaired transformers from 1988 until the early 1990s, mortality from cancer of the intestine was significantly elevated (SMR, 2.6; 95% CI, 1.6–3.5; 11 deaths), but mortality from cancer of the stomach or liver, or leukaemia, was not (Caironi *et al.*, 2005). [This was a small study, but it focused on transformer-repair workers who would have had substantial dermal exposure to PCBs.]

2.1.3 Electric power and telecommunications

Studies of cancer mortality and incidence among workers exposed to PCBs in the electric-power and telecommunications industries have been conducted in Canada (De Guire *et al.*, 1988; Hay & Tarrel, 1997), Italy (Cammarano *et al.*, 1984, 1986), Norway (Tynes *et al.*, 1994), and the USA (Savitz & Loomis, 1995; Loomis *et al.*, 1997; Charles *et al.*, 2003; Table 2.3).

De Guire and coworkers found increased incidence of and mortality from malignant melanoma among 9590 employees of a telecommunications company in Montreal, Canada, who had been employed for 6 months or more between 1976 and 1983 (De Guire *et al.*, 1988, 1992). Three deaths were identified among men (SMR, 3.0; 95% CI, 0.6–8.8), with a stronger association for those with < 20 years latency (SMR, 9.4; 95% CI, 1.1–34; two deaths) than for those with ≥ 20 years latency (one death; SMR, 1.3; 95% CI, 0.0–7.1). Only one case occurred among women (SMR, 4.8; 95% CI, 0.1–27). [This was a reasonably large cohort, but the number of incident cases was small. Exposure to PCBs may have occurred, but was not assessed.]

Cancer incidence among 5088 workers in the hydroelectric-power industry in Norway employed for at least 1 year between 1920 and 1991 was examined in relation to magnetic fields or electric sparks, and to exposure to PCBs (Tynes *et al.*, 1994). Workers were classified as ever or never exposed to PCBs, based on work histories. The incidence of malignant melanoma was increased in the full cohort (SIR, 1.1; 95% CI, 0.7–1.8) and among power-supply electricians (SIR, 2.1; [95% CI, 1.0–3.7]). Significantly increased incidence was also reported among workers ever exposed to PCBs and to > 15 μT-years of magnetic fields (SIR, 2.7; [95% CI, 1.2–5.2]). [This study investigated exposure to PCBs and to electric and magnetic fields. Exposures to PCBs and to electric and magnetic fields may be correlated through associations with certain jobs, but exposure is unlikely to confound the association with PCBs, as such exposure is not known to be associated with melanoma.]

Loomis and colleagues assessed risk of cancer in relation to PCB exposure among 138 905 male employees of five utility companies in California, North Carolina, Pennsylvania, Tennessee, and Virginia, USA, who were employed for at least 6 months between 1950 and 1986 (Savitz & Loomis, 1995; Loomis *et al.*, 1997). Exposures were assessed jointly by representatives of employees and management and by industrial hygienists. Mortality from melanoma increased with increasing exposure to PCBs, from 1.2 (95% CI, 0.6–2.5) for those with < 2000 hours cumulative

EMF, electromagnetic fields; mo, month; OR, odds ratio; PAH, polycyclic aromatic hydrocarbon; PCB, polychlorinated biphenyl; RR, rate ratio; SIR, standardized incidence ratio; SMR, standardized mortality ratio; wk, week; yr, year

exposure to PCBs, to 1.7 (95% CI, 0.7–7.1) among those with 2000–10 000 hours cumulative exposure, to 1.9 (95% CI, 0.5–7.1) for those with > 10 000 hours of cumulative exposure over their career. When exposure was lagged by 20 years, the respective relative risks were 1.3 (95% CI, 0.8–2.2), 2.6 (95% CI, 1.1–6.0), and 4.8 (95% CI, 1.5–15.0). When the risk of melanoma was modelled with a continuous variable for cumulative exposure to PCBs, the relative risk per 2000 hours of exposure was 1.05 (95% CI, 1.01–1.09) with a 20-year lag. There was no association with cancer of the liver, and the association with cancer of the brain was less strong: the relative risk was 1.6 (95% CI, 0.9–3.0) among those with < 2000 hours cumulative exposure and 1.8 (95% CI, 0.8–4.0) among those with 2000–10 000 hours cumulative exposure, but there were no deaths from cancer of the brain among those with > 10 000 hours cumulative exposure (Loomis *et al.*, 1997).

A nested case–control study within this utility-worker cohort investigated mortality from cancer of the prostate relative to exposure to electromagnetic fields and PCBs (Charles *et al.*, 2003). Cases were 387 prostate-cancer decedents; 1935 controls (5 per case) were randomly selected from the risk sets of the cases. The odds ratio for cumulative exposure to PCBs for ≥ 2821.4 hours and mortality from cancer of the prostate, adjusted for age and race, was 1.2 (95% CI, 0.8–1.7). For workers with ≥ 2763.2 hours of exposure to PCBs and ≥ 4.4 μT years of exposure to magnetic fields, the adjusted odds ratio was 1.5 (95% CI, 1.0–2.2).

[The Working Group considered that, because of the size of the cohort and the efforts to assess exposure, the Loomis–Charles studies were the strongest in this group, especially the results showing an exposure–response effect. The lagged analysis of melanoma mortality was informative about exposure-time windows.]

Some information about cancer risk among electrical workers with exposure to PCBs was reported in two smaller studies. Hay & Tarrel (1997) investigated mortality in 1958–1991 among power-company workers in Canada who applied mixtures of the pesticides 2,4-D (2,4-dichlorophenoxyacetic acid) and 2,4,5-T (2,4,5-trichlorophenoxyacetic acid) and waste transformer oil that contained up to 10% PCBs. All-cancer mortality was increased among workers who first sprayed in 1958 or earlier (SMR, 1.5; 95% CI, 0.9–2.3; 18 deaths), but not among those first exposed in 1959 or later, when used transformer oil was added to the pesticide mix (SMR, 1.1; 95% CI, 0.2–3.2; three deaths). [The Working Group noted that the results were not presented by cancer site and concluded that exposures to PCBs were likely to have been negligible.]

Mortality until 1985 was investigated among 270 men who had worked for at least 6 months in a thermoelectric power plant in Italy and who were exposed to PCBs, chromium, nickel, beryllium, polycyclic aromatic hydrocarbons (PAHs), asbestos, and hydrazine (Cammarano *et al.*, 1984, 1986). Among workers with > 10 years exposure, 18 cancer deaths occurred [SMR, 2.2; 95% CI, 1.3–3.4] (Cammarano *et al.*, 1986). [The Working Group noted that workers were exposed to several human carcinogens and that the study was very small, with only one death for most cancer sites, making it difficult to interpret site-specific mortality.]

2.1.4 Miscellaneous industries

As PCBs have been used in many applications, workers in many industries have been exposed, and as structures and equipment that contain PCBs are repaired, demolished, or replaced, workers involved in these operations and/or in waste recycling and disposal may be exposed. There have been many reports of PCB exposure levels and existing or potential health effects associated with exposure to materials containing PCBs, but studies of cancer are very limited.

Robinson *et al.* (1999) conducted a proportionate mortality study of 31 068 deceased,

unionized, electrical workers employed in the construction industry, who might have been exposed to PCBs (and other agents) during their working lives. Excess mortality occurred for melanoma (proportionate mortality ratio, PMR, 1.23; 95% CI, 1.02–1.47) and cancer of the prostate (PMR, 1.07; 95% CI, 1.00–1.14). [Although this very large death-certificate study found an excess risk for cancers that have been associated with exposure to PCBs in other PCB-exposed cohorts, exposure in this cohort could not be confirmed.]

Unspecified industrial uses of PCBs have been associated with an increased risk of cancer. Bahn and colleagues reported two cases of malignant melanoma among 31 workers in research and development and refinery industries in New Jersey, USA, who were exposed to PCB mixtures, where 0.04 cases would be expected [SIR, 50.0; 95% CI, 5.6–217] (Bahn *et al.*, 1976).

2.2 Cohort studies of environmental exposure

2.2.1 Accidental exposure to PCBs

(a) Cancer mortality in Yusho patients, Japan

The first evaluation by IARC of the possible carcinogenic risk of human exposure to PCBs reported the accidental exposure to PCBs through ingestion of rice oil contaminated by Kanechlor 400 in 1968 in western Japan (see Section 1). In an early analysis of deaths occurring up to 5.5 years after exposure among 1200 Yusho patients, nine deaths from malignant neoplasms were reported, including three tumours of the stomach, two tumours of the lung, one cancer of the liver, one of the breast, and two lymphomas (Urabe, 1974; Kuratsune, 1976). A first update considered mortality among 1761 Yusho patients followed up until 1983 (Kuratsune *et al.*, 1988). Among men, there was a statistically significant increase in mortality from all neoplasms (SMR, 2.13; 95% CI, 1.5–3.0), and particularly cancer of the liver (SMR, 5.6; 95% CI, 2.6–10.7), and lung (SMR, 3.2; 95% CI, 1.4–6.3). No statistically significant increase in tumours was reported among the women.

After these early reports, two other mortality analyses of this cohort have been published with follow-up periods up to 1990 and up to 2007 respectively (see Table 2.4). The first report (Ikeda & Yoshimura, 1996) analysed the mortality of 1815 patients (916 men and 899 women), with an average follow-up of 17 years. In the 40-year follow-up of the total of 1918 patients registered as of 31 December 2007 (Onozuka *et al.*, 2009), 254 cases who had not been diagnosed as Yusho from the beginning of the incident were excluded, leaving 1664 cases for analysis (860 men and 804 women). Of the 269 deaths among men, there was a significant excess mortality from all cancers (SMR, 1.37; 95% CI, 1.11–1.66), and from cancers of the lung (SMR, 1.75; 95% CI, 1.14–2.57) and liver (SMR, 1.82; 95% CI, 1.06–2.91). For women, mortality for cancer of the liver was in excess, although not significantly so (SMR, 1.95; 95% CI, 0.78–4.01). Analysis of different periods since the incident showed that the increased risk for all malignancies, and for cancers of the lung and liver tended to decrease over time.

A more recent analysis that did not exclude the 254 patients diagnosed after 1977 (Yoshimura, 2012) reported essentially the same pattern of mortality, with slightly weaker standardized mortality ratios for cancers of the lung and liver (Table 2.4).

Finally, another analysis of mortality of Yusho patients followed up until 2007 was restricted to the area of Tamamoura in the Goto Archipelago (Nagasaki prefecture), because it was the most severely affected (Kashima *et al.*, 2011). Standardized mortality ratios for all cancers, lung cancer, and liver cancer were estimated using the rates of Nagasaki prefecture as the reference and compared for the years 1968–77 and 1978–2002. A slight excess cancer of the

PCB, polychlorinated biphenyl; SMR, standardized mortality ratio

lung was observed in Tamamoura in 1968–77 (SMR, 1.37; 95% CI, 0.76–2.48) [data for cancer of the liver not reported for that period] and no increase in mortality was seen during the later period (Table 2.4). However, significant excess mortality for all cancers, and for cancers of the lung or liver, were observed for the rest of the Goto Archipelago (excluding Tamamoura) in 1978–2002.

[The Working Group noted that excess cancer mortality was largely restricted to men. In addition the excesses of cancers of the lung and liver were observed in the full population of Yusho patients in analyses using national references rates, but not in the subset from the Tamamoura area analysed using local reference rates. Important confounders such as tobacco smoking for cancer of the lung, or viral hepatitis for cancer of the liver could not be taken into account directly, although they may have been partially controlled for by using local reference rates, if the distribution of such confounders in the local reference population were similar to that of the study population. Yusho patients were also exposed to PCDFs. The possibility of confounding by other exposures therefore could not be completely ruled out.]

(b) Cancer mortality in Yucheng patients, Taiwan, China

In 1979, about 10 years after the incident in western Japan, a similar food poisoning incident occurred in three counties (Taichung, Changhua, and Miaoli) of central Taiwan, China (see Section 1). About 2000 residents from these counties had ingested rice oil contaminated with PCBs, and showed clinical manifestations similar to those described for Yusho (skin eruptions and pigmentation, ocular hypersecretion, and peripheral neuropathy); the syndrome was named 'Yucheng' ('oil disease' in Chinese) (see Section 4). Two mortality analyses have been carried out on this exposed cohort, after 12 and 24 years of follow-up, and are summarized in Table 2.4. The first study cohort was based upon 2038 cases registered until 1979; after excluding 99 cases for which vital status could not be assessed, 1940 [sic] Yucheng patients (929 men, 1011 women) remained for analysis of mortality (Hsieh *et al.*, 1996). During 1980–91, 11 deaths from malignancies were observed (8 men, 3 women); overall and sex-specific mortality was non-significantly lower than among the general population, using either local or national reference rates. Data for specific tumour sites were sparse, and included one death from Hodgkin lymphoma and two deaths from cancer of the liver (one man and one woman). Another analysis of the same study population was conducted with the same follow-up (1980–91), but further exclusions, leaving 1837 patients for analysis and 10 observed deaths from cancer (Yu *et al.*, 1997). Although the standardized mortality ratio for all cancers differed substantially from that in the previous analysis, it was not significantly different from that expected based on national rates (SMR, 1.2; 95% CI, 0.6–2.3). Data for specific cancer sites were not reported. [The Working Group noticed the discrepancy between estimates of standardized mortality ratio based upon apparently very similar data sets.]

Data for updated analyses of Yucheng patients are shown in Table 2.4. Tsai *et al.* (2007) extended the follow-up to 2003. From a list of 2061 registered patients, 70 exposed in utero and 168 who could not be traced were excluded, leaving 1823 patients. Forty-one deaths by cancer were observed between 1980 and 2003. Mortality from all neoplasms was not statistically different from that in the population in Taiwan, China, overall or by sex; mortality from cancers at several sites, including liver, lung, and the lymphatic and haematopoietic system, was also similar to that of the national population. As in a previous study, mortality from chronic liver disease and cirrhosis was significantly increased. [The Working Group noted that chronic liver disease and cirrhosis are important risk factors for cancer of the liver,

together with infection with hepatitis B and C viruses, and tobacco smoking.]

A second updated analysis of Yucheng patients extended the follow-up to 2008 (Li *et al.*, 2013). As referents for comparison, the authors used subjects from the registry set up in 1979, residents of the same community, of the same sex and age (within 3 years) as the Yucheng patients, but who did not meet the criteria to be considered as Yucheng patients. After exclusions because of missing or inconsistent data, a total of 1803 Yucheng subjects and 5170 neighbourhood referents were considered for analysis; a total of 67 Yucheng patients died from cancer during 1980–2008. No significant association with all cancer mortality was found overall or among women. Among men, increased mortality was reported for cancer of the stomach (SMR, 3.5; 95% CI, 1.5–7.0, seven deaths) and neoplasms of lymphatic and haematopoietic tissue (SMR, 3.0; 95% CI, 1.1–6.6, five deaths). Mortality from cancer of the liver was elevated among women (SMR, 2.1; 95% CI, 0.9–4.5, six deaths), but not among men (SMR, 0.4; 95% CI, 0.1–1.1, four deaths). [The neighbourhood referent population used in this study may also have been exposed, which would lead to underestimation of relative risks.]

[The Working Group noted that the excess mortality from all cancers and tumours of the liver observed in Yusho patients was not present in Yucheng patients. The composition of PCDF isomers differed markedly between the two incidents: the main PCDF isomer in Yusho patients was 2,3,4,7,8-pentachlorinated dibenzofuran, which has a higher toxic equivalency factor than the main isomer affecting Yucheng patients, 1,2,3,4,7,8-hexachlorinated dibenzofuran (Onozuka *et al.*, 2009). On the other hand, no excess mortality for cancers of the stomach or lymphatic and haematopoietic tissue was observed in the Yusho patients. The same other limitations mentioned for the Yusho cohort applied to the Yucheng studies: residual confounding, or chance due to multiple comparison made in these analyses could not be discounted.]

2.2.2 Dietary exposure to PCBs

See Table 2.5

Apart from incidental contamination, chronic exposure to PCBs may occur through a diet rich in foods with a high content of PCBs; such exposure has been observed in northern Europe in populations with a high consumption of fish.

Cohorts of fishermen from the east coast and west coasts of Sweden were established in 1968 and 1965 respectively (Rylander & Hagmar, 1995; Svensson *et al.*, 1995). Women who were, or had been, married to these fishermen were identified from national and local population registries. After exclusion because of death, divorce, or emigration, the respective cohorts of fishermen's wives included 1986 women on the east coast and 6605 women on the west coast (Rylander & Hagmar, 1995). Information on vital status and cancer incidence up to 1989 was gathered from Swedish statistics and the Swedish cancer registry. Cancer incidence was compared directly between the cohorts on the east coast (contaminated) and west coast (control), with adjustment for age and calendar year. The incidence rate ratio (IRR) for all cancers was 1.19 (95% CI, 1.00–1.41). Among specific cancer sites, risk was increased for cancer of the breast (IRR, 1.35; 95% CI, 0.98–1.86), cervix (IRR, 1.93; 95% CI, 0.83–4.50) and corpus uteri (IRR, 1.16; 95% CI, 0.61–2.20). All cancer mortality was also significantly more elevated in the east-coast cohort when compared with the regional rates (SIR, 1.17; 95% CI, 1.00–1.36). Dietary information showed modest differences in consumption of fatty fish between the east and west coasts. In a recent update extending the follow-up until 2002 (Mikoczy & Rylander, 2009) expected mortality and cancer incidence were based on national

rates, and no direct comparison between east- and west-coast cohorts were reported. Standardized mortality ratios for all cancers combined were 0.98 (0.91–1.06) for the west-coast cohort and 1.15 (95% CI, 0.98–1.34) for the east-coast cohort. Statistically significant excess incidence was reported for cancer of the colon in the east-coast cohort (SIR, 1.61; 95% CI, 1.14–2.21) and non-melanoma cancer of the skin in the west-coast cohort (SIR, 1.43; 95% CI, 1.09–1.84). [The Working Group noted that the excess of cancer incidence observed using regional rates as reference became nonsignificant when national rates were used. Because of the lack of specific exposure information, the possibility of confounding cannot be ruled out.]

In Finland, a cohort of Baltic Sea fishermen was identified from the Professional Fishermen Register, and their wives were identified from the Population Register (Turunen *et al.*, 2008). A cohort of 4260 women was linked with Statistics Finland's national cause-of-death data from 1980 to 2005, and expected deaths were calculated according to national rates. Furthermore, a cross-sectional substudy was conducted among 94 cohort participants who undertook a health examination in 2004–2005, including a food-frequency questionnaire and fasting-blood collection; data from a population-based survey were used for comparison. No statistically significant standardized mortality ratios were found for all cancers, or for any specific tumour site.

After an accidental spill of oil contaminated with PCBs from the brass works industry in Gusum, Sweden, in 1972, elevated levels of PCBs were measured in local fish in 2006. Among the population of the contaminated area, 641 cases of cancer were identified in 1960–2003, which was not above the expected number based on national rates for the same period (Helmfrid *et al.*, 2012). Among men, 22 lymphomas were observed, with a statistically significant increased standardized incidence ratio (SIR) of 1.60 (95% CI, 1.00–2.42). There was also an increased risk of cancer of the testis (SIR, 2.46; 95% CI, 0.99–5.08; seven cases) and malignant melanoma of the skin (SIR, 1.56; 95% CI, 0.87–3.94) in the contaminated area when compared with the general population, while the risk for cancer of the prostate was near unity (SIR, 1.06; 95% CI, 0.86–1.29). In addition to the cohort analysis, a case–control study based upon a dietary questionnaire was carried out on 67 cases of cancer, including cancers of the colorectum, skin (including melanoma), cervix, breast, prostate, and lymphoma, and 326 controls resident in the same area. The case–control analysis reported an increased risk of cancer of the female breast associated with consumption of fish more than twice per month, but with only two cases. Excess risks of lymphoma (five cases, including men and women) were also observed with consumption of fish more than twice per month. Consumption of locally produced foods was also analysed, but no other statistically significant increased risks associated with potential sources of exposure to PCBs were reported in the case–control analysis. [The Working Group noted that subjects from this area could have also been exposed to other contaminants, such as metals. The case–control analysis was based upon a very small number of subjects, and there was poor assessment of dietary exposure and control for potential confounders.]

Regular consumption of predatory fish constitutes a large source of exposure to several persistent pollutants, including PCBs, for residents of the Great Lakes Basin (Falk *et al.*, 1999). A cohort of regular consumers of sport fish from the Great Lakes, and residents in the same communities who consumed no sport fish from the Great Lakes (referents), were recruited in 1993–94 (Tomasallo *et al.*, 2010). A total of 3757 subjects (2275 fish consumers and 1482 referents) were followed from 1995 to 2006, and mortality was compared with national death rates. Information about fish consumption and other lifestyle characteristics was obtained by telephone interview, and a blood sample for measurement of PCBs

was collected for a subgroup of 610 individuals. During the 12-year follow-up period, 342 deaths were recorded, including 134 deaths from cancer. Cancer mortality rates did not differ from those of the general population for fish consumers or referents: SMRs for all cancers were 0.92 (95% CI, 0.74–1.13) and 0.87 (95% CI, 0.64–1.13), respectively. However, fish consumers had non-statistically significant excesses of cancers of the pancreas, brain and combined breast, uterus and ovary. Although blood PCB levels were positively associated with fish consumption among fish consumers ($P < 0.001$ for comparison of mean PCB concentrations according to three levels of fish consumption), there was no association between fish consumption and cancer mortality. [The Working Group regarded this study as informative because it included information about PCB exposures, as well as fish consumption. However, the possibility of confounding from concurrent exposure to other contaminants could not be ruled out.]

[Compared with cohorts of Yusho or Yucheng patients, who consumed food contaminated with a high level of PCBs for a short period, potential exposure to PCBs through diet is a long-term, low-level exposure. Fish or local vegetables contaminated by PCBs are often also contaminated by other compounds such as DDT, PCDFs, PCDDs, or heavy metals. Furthermore, as detailed information on other risk factors for the tumours analysed (i.e. lymphoma, breast, colon, skin) was lacking, residual confounding could not be ruled out as a potential explanation for the associations found in these studies.]

2.2.3 Nested case–control studies of PCB concentrations in blood or adipose tissue

Since the 1980s, several cohort studies have addressed the potential relationship between risk of cancer and internal measurements of exposure to PCBs. The most commonly used marker of past exposure to PCBs is the serum or plasma concentration of a set of PCB congeners, although a few studies have measured PCB concentrations in adipose tissue. Most studies used a case–control design nested within a cohort as an efficient method for analysis: PCB concentrations were measured in all incident cases diagnosed within a defined follow-up period, and in a sample of at-risk subjects (controls) selected within the same cohort. A few studies have used a case–cohort approach, in which the referent group is formed by a random sample of the whole cohort selected at baseline. Various sets of PCB congeners were measured; PCB-118, PCB-138, PCB-153, and PCB-180 were reported more often because they were frequently analysed and prevalent in human biological samples (see Section 1.2 for more information on analytical methods). In some instances results for individual congeners were provided but, unless otherwise specified, the summary estimate refers to the sum of all measured PCBs.

(a) Cancer of the breast

See Table 2.6

(i) USA

The New York University Women's Health Study (NYUWHS) enrolled 14 290 women from New York City between 1985 and 1991; these women donated a 30 mL blood sample while attending a mammography screening clinic (Wolff *et al.*, 1993). During this period, women who were diagnosed with cancer of the breast 1–6 months after entry into the study were defined as cases. Controls were selected at random from all cohort members who were alive and free of cancer at the time of the cancer diagnosis in a case patient, matched on menopausal status, age at entry and day of menstrual cycle at the time of blood collection. Concentrations of PCBs were measured without correction for serum lipids. [Since cases were diagnosed only 1–6 months subsequent to entry, the disease

could have been present when the blood sample was collected, despite negative mammography findings, and could therefore have affected the measured concentration of PCBs.] Additional cases and controls were included in an extended follow-up of this cohort to 1994, giving totals of 148 cases and 295 controls (Wolff *et al.*, 2000a). In this update, only incident cases were considered (thus excluding those with a lag time of 6 months or less). Serum lipids were measured and PCB concentrations were calculated on a lipid basis. The risk estimates were further adjusted for family history of cancer of the breast, reproductive risk factors, height, and body mass index (BMI). Odds ratios increased across quartiles of serum PCB concentrations, reaching 2.02 (95% CI, 0.76–5.37) in the highest quartile; the trend was not statistically significant. [The Working Group noted that this was a well-designed study; however, the follow-up was relatively short and the analysis thus had limited power.]

Krieger *et al.* (1994) performed a nested case–control study among women in Northern California, USA, who were members of the Kaiser Permanente Medical Care Program and who underwent a health examination, including giving a sample of blood, between 1964 and 1969, and were followed up until 1990. Among the 2072 patients identified with cancer of the breast, 150 cases were randomly selected (50 white, 50 black, and 50 Asian) and matched to 150 controls by race, age, date of entry, and date of follow-up. After adjustment for reproductive factors, menopausal status and BMI, no association was seen between risk of cancer of the breast and serum PCB concentrations for all subjects (OR, 0.93; 95% CI, 0.83–1.05 per ppb). In subgroup analyses by ethnic group, there was an inverse association for white women (OR, 0.21; 95% CI, 0.05–0.88; and OR, 0.17; 95% CI, 0.03–0.89 for the second and third tertiles respectively, *P* for trend = 0.04) and a positive association for black women (OR, 1.74; 95% CI, 0.56–5.43 and OR, 2.13; 95% CI, 0.70–6.50, respectively, *P* for trend = 0.18). [This was a well-designed study with adjustment for relevant confounders, with more than 2000 cases of cancer of the breast identified during the follow-up; however, only 150 were selected for measurement of PCBs and thus power was limited, especially for subgroup analyses.]

The Nurses' Health Study was established in 1976 and included more than 120 000 registered nurses in the USA, who were subsequently followed by questionnaire every 2 years and 32 826 women from the cohort provided a blood sample between 1989 to 1990. Results were reported from follow-ups until 1992 (Hunter *et al.*, 1997) and 1994 (Laden *et al.*, 2001a). In the first follow-up, no association was found between cancer of the breast and PCB concentrations after adjustment for family history of cancer of the breast, reproductive factors, BMI, and cholesterol (Hunter *et al.*, 1997). The extended follow-up to 1994 included 370 case–control pairs, and provided results for individual congeners (Laden *et al.*, 2001a). The pattern of risk by quintile did not change and no association was found for PCB-118, PCB-138, PCB-153, or PCB-180. In subgroup analyses, a significant increase in risk was reported for exposure to the sum of 16 PCBs in nulliparous women (OR, 5.30; 95% CI, 1.06–26.6 for the third tertile of PCB serum concentrations when compared with the first tertile, but the overall trend was not significant; $P = 0.11$). An inverse association was found for women with BMI ≥ 30; the odds ratio for the highest versus lowest tertile was 0.26 (95% CI, 0.09–0.76; *P* for trend = 0.01), while elevated odds ratios were found for women in the highest tertile of PCB exposure with BMI of 25–29.9 and < 25. Since PCB exposure induces activity of cytochrome P450 1A1 (CYP1A1), and PCBs themselves can be metabolized to carcinogenic intermediates by this enzyme, it was explored whether the potential effect of PCBs was modified by the CYP1A1 polymorphism using the same data set (Laden *et al.*, 2002). In 367 case–control pairs, *CYP1A1* exon 7 and *MspI* polymorphisms

were determined. The relative risk increased across tertiles of PCB exposure among those with the variant exon 7 genotype, but not among those with the wild-type genotype. When the analysis was restricted to postmenopausal women, the odds ratio was 2.78 (95% CI, 0.99–7.82) for the highest tertile of PCB exposure, with a *P* value for interaction of 0.05. No gene–environment interaction was seen for *MspI* polymorphism. [The Working Group noted that this was a well-designed study with good controls for most relevant confounders, including reproductive factors and family history of cancer of the breast. The sample size was reasonable when compared with previous studies, and estimates for specific PCB congeners were reported. The only statistically significant associations were limited to specific subgroups after several subgroup analyses and multiple comparisons.]

In another study in the USA, 7224 female volunteers were identified through the Breast Cancer Detection and Demonstration Project (BCDDP) and donated blood to the Columbia Missouri Breast Cancer Serum Bank; active follow-up continued until 1989 (Dorgan *et al.*, 1999). Among these women, 105 were diagnosed with histologically confirmed cancer of the breast, and two controls for each were selected, matched on year of age, date of blood sampling, and history of benign breast disease at the time of enrolment. No association was reported between risk of cancer of the breast and lipid-corrected concentrations of total PCBs (sum of 27 PCB congeners measured), or serum concentrations of PCB-118 and PCB-138, after adjustment for the main risk factors for cancer of the breast. [This study had a relatively small number of cases and was therefore of limited power].

A case–control study was conducted among residents of Washington County, Maryland, USA, who had participated in one of two studies conducted in 1974 and 1989 to obtain blood samples for a serum bank (Helzlsouer *et al.*, 1999). Participants were followed up until 1994 by linkage with the Washington County Cancer Registry. Of the 346 cases of cancer of the breast diagnosed, valid measurements of PCBs were available for 340 cases, which were matched to 340 participating women without cancer of the breast by age, menopausal status and date of blood collection. Taking into account relevant confounders including family history of cancer of the breast, reproductive history and BMI, no association was found with total PCB serum concentration or with specific congeners. There were no statistically significant associations after stratifying for menopausal status, estrogen-receptor (ER) status or polymorphism in *GSTM1*, *GSTT1*, *GSTP1*, *COMT*, or *CYP17*. [The Working Group noted that this study, with an analysis adjusting for most relevant confounders, investigated the hormone-receptor status of tumours, and also considered possible effect modification by polymorphisms in several genes with a role in metabolism. Although the sample size was adequate for the main analysis, it was limited for subgroup analyses.]

A nested case–control study compared serum concentrations of 16 PCBs in archived early-postpartum serum samples collected between 1959 and 1967 from 112 cases of cancer of the breast and 112 age-matched controls (Cohn *et al.* 2012). Subjects were residents of Oakland, California, participating in the Child Health and Development Studies. Cases of cancer of the breast were identified by linkage to the California Cancer Registry, and the California Vital Status Records. The median time from blood draw to diagnosis was 17 years, and mean age of cases at diagnosis was 43 years. No associations were reported between risk of cancer of the breast and sum of total PCBs, or with PCB groups (Wolff *et al.*, 1997). [No odds ratios were reported for these analyses]. PCB-167 was associated with a lower risk (OR for highest versus lowest quartile, 0.2; 95% CI, 0.1–0.8), as was PCB-187 (OR for highest versus lowest quartile, 0.4; 95% CI, 0.1–1.1). In contrast, PCB-203 was associated

with an increased risk (OR for highest versus lowest quartile, 6.3; 95% CI, 1.9–21.7). [This was the only nested case–control study to include mostly premenopausal women. The study had limited power.]

(ii) Northern Europe

Serum samples were obtained in 1976 from a cohort of 7712 women aged 20 years or older who participated in the Copenhagen City Heart Study (Denmark) and provided information and a non-fasting blood sample (Høyer *et al.*, 1998). Case ascertainment was achieved by linkage to the Danish Cancer Registry up to 1993. For each case, two women free of breast cancer and alive at the time of diagnosis and matched for age and date of examination were selected from the rest of the cohort. After excluding subjects without a valid serum sample, 240 cases and 447 controls were included in the study. Concentrations of 28 PCB congeners were measured in serum. No association was reported between risk of cancer of the breast and lipid-adjusted concentrations of the sum of PCBs or specific congeners.

Participants in the same cohort study were invited for a second examination 5 years after recruitment; 155 cases and 274 controls from the previous study had a second serum sample available (Høyer *et al.*, 2000). Analyses were carried out in this group for four common PCB congeners. A statistically significant increased risk and trend was found for subjects in the highest quartile of PCB-138 concentration (average of two measurements; OR, 2.1; 95% CI, 1.0–4.4; *P* for trend = 0.04). Elevated odds ratios were reported for the highest quartile of exposure to total PCBs and congeners PCB-118 and PCB-153 (OR, 1.6, 1.9 and 1.3, respectively), but the association was not significant for these congeners or for PCB-180.

Within the same cohort, a total of 161 cases with ER status information and 318 matched controls who were free of breast cancer were included in an analysis according to ER status (Høyer *et al.*, 2001). No association was found between incidence of cancer of the breast and PCB concentrations regardless of ER status. Finally, paraffin embedded tumour-tissue specimens were retrieved for 162 cases and 316 controls and found to be suitable for *p53* analysis (Høyer *et al.*, 2002). A non-significant increased risk of cancer of the breast (OR, 3.00; 95% CI, 0.66–13.62) was observed in the highest level of exposure to PCBs among women with mutant *p53*. [Several analyses were carried out using data from this Danish study, but power was limited, particularly for subgroups.]

The JANUS Serum Bank contains serum samples collected between 1973 and 1991 from almost 300 000 individuals undergoing routine health examinations in Norway. Cases of cancer of the breast were identified among 25 431 women working outside home and resident on a farm who were followed until 1993 through linkage with the Norwegian Cancer Registry (Ward *et al.*, 2000). From the 272 cases diagnosed during this period, 150 women with a blood sample taken 2 or more years before diagnosis were randomly selected; an equal number of controls were matched to cases by date of sample collection and date of birth. The mean lipid-corrected concentration of serum PCBs (sum of 36 congeners) was similar for cases and controls (*P* value, 0.47 for paired *t*-test). No association was found for specific PCB congeners or for PCB groups as defined by Wolff *et al.* (1997). [The Working Group noted that this study was well designed and considered most relevant confounders for cancer of the breast but, similar to other nested case–control studies with serum PCB measurements, had limited power.]

Between 1993 and 1997, 29 875 Danish women aged 50 to 64 years were enrolled in a prospective study of diet and cancer and followed until December 2000 through linkage with Danish Cancer Registry (Raaschou-Nielsen *et al.*, 2005). During this period, 409 women were diagnosed with postmenopausal cancer of the breast; each case was matched to one control by age,

postmenopausal status (known/probable), and use of hormone replacement therapy, and measurements of 18 PCBs in adipose-tissue biopsies were obtained. No association was found between concentrations of PCBs and risk of cancer of the breast in the whole data set. However, an inverse association was observed when the analysis was restricted to the 75 ER-negative (ER–) cases (OR, 0.3; 95% CI, 0.1–0.9). This inverse association for ER– cases was also observed for the congeners PCB-138, PCB-153, PCB-170, PCB-180, PCB-183 and PCB-187. [The Working Group noted that this was the largest nested case–control study of cancer of the breast with PCB measurements, and the only one to measure PCBs in adipose tissue rather than serum. The inverse association of concentrations of total PCB and some PCB congeners among women with ER– tumours does not have a clear interpretation.]

(b) NHL

See Table 2.7

(i) USA

Seventy-four cases of NHL (ICD-8 200 or 202) identified during follow-up from 1975 to 1994 of the cohort from Washington County, Maryland, USA (described in the previous section) and 147 controls matched by race, sex, and age were included in a case–control study (Rothman *et al.*, 1997). PCB concentrations were measured in serum collected before diagnosis and corrected for lipids. There was a significant dose–response relationship between risk of NHL and quartiles of lipid-corrected serum concentrations of PCBs (sum of 28 measured congeners). The odds ratios for the third and fourth quartiles when compared with the first quartile were 2.8 (95% CI, 1.1–7.6) and 4.5 (95% CI, 1.7–12.0) respectively; these estimates were adjusted, in addition to matching variables, for education, cigarette smoking and occupational exposure to suspected risk factors for NHL. There was also an indication that seropositivity for the Epstein-Barr virus early antigen (EBV-EA) potentiated the effects of serum PCBs, with a statistically significant interaction (*P* value = 0.025).

An analysis of the same data set focusing on the effect of specific congeners reported a significant exposure–response relationship between risk of NHL and increasing concentrations of PCB-118, PCB-138, and PCB-153 (*P* for trend < 0.05) (Engel *et al.*, 2007). [The Working Group noted that this was the only nested case–control study on PCB concentrations and NHL that adjusted for occupational exposure to potential risk factors.]

An analysis of the association between NHL and exposure to PCBs conducted within the Nurses' Health Study cohort (described in the previous section) was reported in the same publication (Engel *et al.*, 2007). Thirty women with incident NHL diagnosed between the date of blood collection and May 1994 (median follow-up, 1 year) were included as cases and 78 cohort members selected previously as controls for a study of cancer of the breast served as controls. Plasma samples were analysed for PCB concentrations for cases and for controls at the same time. A statistically significant exposure–response relationship was observed between risk of NHL and increasing concentrations of lipid-corrected PCBs (sum of 21 congeners), with an odds ratio of 4.7 (95% CI, 1.2–18.9) for the third tertile, adjusted for age, BMI, and smoking status. A significant exposure–response relationship was also observed for PCB-118 and PCB-138 (*P* for trend < 0.05), but not for PCB-153.

An extended follow-up of the Nurses' Health Study cohort (median time to diagnosis, 5.8 years) included 145 cases of NHL and selected two controls for each case (n = 290) matched on age, race, month of blood draw, and fasting status (Laden *et al.*, 2010). Women with NHL were identified by annual follow-up questionnaires and confirmed by review of medical records and pathology reports. No association was observed between total serum concentrations of PCBs

Table 2.7 Nested case-control studies on risk of non-Hodgkin lymphoma and measured serum or adipose concentrations of PCBs

Reference, location follow-up period	Total subjects	Exposure assessment	Subgroup analysis	Exposure categories	Exposed cases	Relative risk (95% CI)	Covariates Comments
USA							
Rothman *et al.* (1997) Maryland, USA 1972–1990 until 1994	25 802 adults; 74 cases, 147 controls	Serum, GC/ECD, lipid-corrected concentrations		Quartiles of PCB concentration (ng/g lipid)			Race, sex, age (matching), education, cigarette smoking, potential for occupational exposure

[a] Congeners measured: PCBs 28, 52, 56, 74, 99, 101, 105, 110, 118, 138, 146, 153, 156, 170, 172, 177, 178, 180, 183, 187, 189, 193, 194, 195, 201, 203, and 206

[b] Immunotoxic congeners: PCB-66, PCB-74, PCB-105, PCB-118, PCB-156, and PCB-167

[c] Ninety-nine percent of samples had concentrations greater than the limit of detection for PCB congeners 74, 118, 138, 146, 153, 156, 170, 180, 187, 194, 196, 199, 203, 206, and 209

[d] Congeners measured: PCBs 126, 169, 74, 99, 118, 105, 146, 153, 138, 158, 167, 156, 157, 178, 187, 183, 177, 172, 180, 170, 189, 201, 196, 203, 195, 194, 206, 209; 26 with > 90% samples having concentrations greater than the limit of detection

[e] Congeners measured: PCBs 99, 118, 138, 153, 156, 170, 180, 183, 187, and 201. LOD, 0.10–1.00 ng/g lipid; proportion of subjects with values greater than the limit of detection ranged from 72% (PCB-99) to 100% (PCB-153 and PCB-180)

BMI, body mass index; ECD, electron capture detection; ER, estrogen receptor; FTP, full-term pregnancy; GC, gas chromatography; HRGC, high-resolution gas chromatography; ID-HRMS, isotope dilution high-resolution mass spectrometry; IRR, incidence rate ratio; IQR, interquartile range; LOD, limit of detection; mo, month; NHL, non-Hodgkin lymphoma; NR, not reported; OR, odds ratio; PCB, polychlorinated biphenyl

(sum of 51 congeners measured as lipid-corrected concentrations) or for specific congeners (PCB-118, PCB-138, PCB-153, PCB-180) after adjustment for several confounders. The same pattern of no association was observed in the subgroup analysis by the main subtypes of NHL, diffuse large B-cell lymphoma (DLBCL), follicular lymphoma, and chronic lymphocytic leukaemia/small lymphocytic lymphoma. [This was the only nested case–control study on non-Hodgkin lymphoma to include women only. The Working Group noted that it was a well-designed study. The positive association observed in the initial study was not confirmed in the second, larger study, after adjustment for additional relevant confounders. However, in the second study the time since blood draw was prolonged and different laboratories and laboratory methods were used for analysis.]

The Physicians' Health Study began in 1982 in the USA as a randomized trial for the primary prevention of cardiovascular disease and cancer in male physicians aged 40–84 years at enrolment. A total of 14 916 participants provided a blood sample in 1982–84 (before randomization) and were followed until 2003 using annual questionnaires confirmed by review of medical records to identify newly diagnosed NHL (Bertrand *et al.*, 2010). After excluding those with a diagnosis within 6 months after blood collection, prior diagnosis of cancer, NHL of uncommon subtypes (i.e. mantle cell lymphoma), or lacking sufficient information for subtype classification, 205 cases with available blood samples were included. For each case, two subjects who were at risk of NHL when the case occurred were randomly selected as controls matched by race, age, and date of blood collection. Lipid-corrected concentrations of 51 PCB congeners in serum were determined for cases and controls. The odds ratio for the highest versus lowest quintile of total PCBs adjusted for matching variables was 1.9 (95% CI, 1.1–3.2), which was reduced to 1.6 (95% CI, 0.91–2.9) after adjustment for region, BMI, smoking status, alcohol intake, and height, in addition to matching variables. However, using the natural log of lipid-corrected concentrations of PCBs, the association was statistically significant for the fully adjusted model (P value < 0.01, OR not reported). The association was also significant for the log-concentrations of PCB-138, PCB-153 and PCB-180, as well as for the sum of PCBs -118, -138, -153 and -180. [The Working Group noted that this was a well-designed study with reasonable sample size. The multivariable adjustment weakened the association with total PCBs, but did not substantially change the interpretation.]

(ii) Northern Europe

Within the JANUS cohort, described in the previous section, 194 histologically confirmed cases of NHL were ascertained with follow-up to 1999 (median time to diagnosis, 16.6 years) (Engel *et al.*, 2007). Information, including lipid-corrected concentrations of 36 PCB congeners, was available for 190 case–control pairs matched by age, sex, county, and date of examination. In the analysis further adjustments were made for BMI and smoking status. The odds ratio for the association of NHL with the sum of PCBs was 1.7 (95% CI, 0.8–3.4) when comparing the fourth quartile with the first. A statistically significant increase in risk was reported for the highest to the lowest quartile of PCB-153 concentrations (OR, 2.0; 95% CI, 1.0–3.9), with a significant upward dose–response trend (P < 0.05). Odds ratios of 1.7 in the fourth exposure quartile and significant trends were also reported for PCB-118 and PCB-138. [The Working Group noted that the sample size, and therefore the power of the study, was in the range of that of the remaining nested case–control studies. It was not clear, therefore, why significant associations were found for three congeners, namely PCB-118, PCB-138, and PCB-153, but not for all PCBs combined.]

The association between NHL and PCB concentrations in adipose tissue was also studied among participants in the Danish diet and cancer

study (Raaschou-Nielsen *et al.*, 2005) described in section 2.2.3(a)(ii) (Bräuner *et al.*, 2012). Up to July 2008 (mean follow-up, 9.6 years), 278 initially cancer free cohort members were diagnosed with NHL; a subcohort of 256 participants was randomly selected for analysis using a case–cohort approach. Valid measurements of concentrations of 10 PCB congeners in adipose tissue were available for 239 cases and 245 subcohort members. Age was used as the timescale for the analysis, stratified by sex and adjusted for BMI. No association was observed between lipid-corrected concentrations of total PCBs in adipose tissue and risk of NHL. There was also no consistent association and no significant trend with PCB congeners. However, odds ratios were greater than 1 for all concentrations of PCB-99. [The Working Group noted that this was the largest nested case–control study on NHL and PCB concentrations measured in adipose tissue; estimates were adjusted only for age, sex, and BMI. The study explored the potential effect of all PCBs and a list of 10 specific congeners, with a consistent pattern of no association for all of them.]

(c) Cancer of the male genital tract

See Table 2.8

A nested case–control study on the risk of testicular germ cell tumours was carried out within the Norwegian JANUS cohort, described in Section 2.2.3(a)(ii) (Purdue *et al.*, 2009). Cases and controls were selected from cohort members with baseline blood collection without prior history of cancer. One male control was matched to each case by region, age group (2 years), and year of blood draw. Lipid-corrected measurements of the concentrations of 34 PCBs were available for 49 cases and 51 controls; 34 of the 49 cases were seminomas, 8 were non-seminomas, 5 were of mixed histology, and 2 were of unknown histology. There was no statistically significant association between risk of testicular germ cell tumours and total PCB concentration (OR, 1.3; 95% CI, 0.5–3.8 for the third versus the first quartile); however, there was an increased risk of testicular germ cell tumours for the highest versus the lowest tertile of PCB-99 concentration (OR, 2.2; 95% CI, 0.8–5.9) and of PCB-167 (OR, 4.4; 95% CI, 1.0–19.8). Cases of seminoma had significantly lower concentrations of congeners PCB-44, PCB-49, and PCB-52 and significantly higher concentrations of congeners PCB-99, PCB-138, PCB-153, PCB-167, PCB-183, and PCB-195. Similar patterns of elevated odds ratios were seen for PCB-99 and PCB-167 in this subgroup of cases. [The Working Group noted that this was a well-designed study, but with small sample size and very limited power.]

McGlynn *et al.* (2009) analysed concentrations of 15 PCBs in pre-diagnostic serum samples of 736 incident cases of testicular germ cell tumours and 913 controls matched to the cases on age, race, and serum draw date in a cohort of men in the United States military. The sum of PCB concentrations was significantly associated with decreased risk of all testicular germ cell tumours, and with non-seminoma and seminoma. Statistically significantly decreased risks of all testicular germ cell tumours were also associated with eight specific congeners (PCB-118, PCB-138, PCB-153, PCB-156, PCB-163, PCB-170, PCB-180, and PCB-187). Similar decreases in risk were observed for non-seminoma with the same congeners, while decreased risk of seminoma was associated with PCB-138, PCB-153, PCB-156, PCB-163, and PCB-170. Other congeners and groups of congeners were not associated with testicular germ cell tumours. In another study using data from 568 cases and 698 controls enrolled in the same cohort, Chia *et al.* (2010) examined associations between testicular germ cell tumours and 11 PCB congeners in relation to polymorphisms in hormone-metabolizing genes. A statistically significant reduced risk of testicular germ cell tumour for PCB-118 and PCB-138 was found only among subjects with the major homozygous allele for *HSD17B4*. [These appear

to have been large, well-designed and well-implemented studies, but the consistent inverse associations of cancer risk with exposure to PCBs could not be explained biologically.]

The Japan Public Health Center-based Prospective Study was initiated in 1990. After excluding subjects from Tokyo for whom cancer information was not available, the cohort consisted of 65 657 men, of whom 14 203 (28%) donated blood between 1990 and 1995 (Sawada *et al.*, 2010). Up to December 2005, 201 newly diagnosed cases of cancer of the prostate were identified using several information sources (97% pathologically confirmed). For each case, two controls were selected from among subjects with no history of cancer of the prostate when the case was diagnosed, matched by age (within 3 years), public health-centre area, residence, date and time of day of blood collection, and duration of fasting. Lipid-corrected plasma concentrations of 41 PCB congeners were measured. Apart from matching variables, comparisons between cases and controls were further adjusted for BMI, smoking, alcohol, marital status, and intakes of green tea and miso soup. No statistically significant association with all cancers of the prostate was seen for total PCBs, for individual PCBs, or for PCBs grouped according to Wolff *et al.* (1997). No statistically significant differences were found for total PCBs according to stage (localized or advanced) at diagnosis of cancer of the prostate. [The Working Group noted that this was a well-designed and -conducted study showing null results; although the sample size was limited, power was reasonable for the main analysis, but limited for subgroup analyses.]

2.3 Case–control studies of occupational and environmental exposure

2.3.1 NHL

See Table 2.9

In a case–control study in Australia (Fritschi *et al.*, 2005), including 694 histologically confirmed cases of NHL, and 694 controls, exposure to PCBs was coded by an expert industrial hygienist based on questionnaire information. After adjusting by age, sex, residence and ethnicity, ever exposure to PCBs was not notably related to increased risk of NHL (OR, 1.10; 95% CI, 0.49–2.44) or to the subgroup of B-cell NHL (OR, 1.18; 95% CI, 0.53–2.62); however, risk was elevated among the subjects probably exposed (OR, 4.54; 95% CI, 0.97–21). Indicators of frequency, intensity, and duration of exposure did not show clear trends in risk. Occupational exposure to PCBs was very rare in this study, with only 25 subjects (13 cases and 12 controls) possibly or probably exposed. [The Working Group noted that this general-population case–control study may have been underpowered to detect associations with PCBs, given the low prevalence of exposure.]

A case–control study was conducted in an area of northern Italy where environmental exposure had resulted from soil contamination, most likely generated by spills from an adjacent factory producing PCBs and organochlorine chemicals. PCB concentration in the soil was used to define four areas with increasing concentrations of exposure. Overall, 495 cases of NHL, including 208 prevalent cases and 287 incident cases, identified in the Cancer Registry of the Brescia Local Health Authority, and 1467 population controls, randomly selected from the resident population, frequency-matched to cases by age and sex, participated in the study. Exposure to PCBs was assigned according to residence in one of three contaminated zones or a control zone, using three metrics: main lifetime residence; residence for at least 10 years in a given area; and duration of residence. Risk of NHL was elevated for subjects having resided 10 or more years in any of the three contaminated areas (OR, 1.4; 95% CI, 1.1–1.8), and particularly in the most polluted (OR, 1.9; 95% CI, 0.9–3.9).

Risk was highest for those who had resided 10–19 years in the most polluted area (OR, 3.8; 95% CI, 1.5–9.8) (Maifredi *et al.*, 2011). [The authors used the ICD-9 classification to define NHL, and therefore did not include chronic lymphocytic leukaemia among their cases, which precluded any feasible analysis of specific NHL subtypes.]

Several small case–control studies in Sweden used adipose tissue or serum levels of total PCBs and individual congeners as the exposure indicator. In a first study with 27 cases and 17 controls (Hardell *et al.*, 1996, 1997), risk of NHL was elevated for total PCB concentrations [17 congeners] above the median among controls (OR, 1.8; 95% CI, 0.4–7.4), after adjusting for age and sex. Thirty-six PCB congeners were measured in a second study with 82 cases of NHL and 83 controls. The odds ratio was significantly increased for concentration of immunotoxic PCBs (Moysich *et al.*, 1999a) above the median among the controls (OR, 3.2; 95% 1.4–7.4) (Hardell *et al.*, 2001). An interaction was observed between elevated concentrations of total and immunotoxic PCBs above the median and EBV-EA antibodies: EBV-EA seropositivity (EBV-EA antibody titre >80) and adipose total PCB concentrations were associated with an increase in risk of NHL of two- to fourfold, which was highest when the immunotoxic PCB subgroup was considered (OR, 6.4; 95% CI, 1.9–24). When the low-grade B-cell NHLs were analysed separately, risk associated with elevated median concentrations of immunotoxic PCBs among subjects with EBV-EA seropositivity was increased 17-fold (95% CI, 3.1–150; 16 cases) (Hardell *et al.*, 2001).

Another case–control study in Sweden included 99 cases of NHL and 99 population controls, matched to cases by age, sex, and health-service region (Hardell *et al.*, 2009). After adjusting by age, sex, and BMI, risk of NHL was elevated for values above the median among controls for the sum of PCBs (OR, 2.0; 95% CI, 0.99–3.9), and to a lesser extent for the subgroups of moderately chlorinated PCBs, highly chlorinated PCBs, or immunotoxic PCBs. Risk was highest for follicular lymphoma for the subgroup of highly chlorinated PCBs (OR, 9.6; 95% CI, 1.9–49; 18 cases); immunotoxic PCBs (OR, 3.0; 95% CI, 0.9–11); and less chlorinated PCBs (OR, 2.8; 95% CI, 0.9–9.0). Risks were only moderately and non-significantly elevated for diffuse large B-cell lymphoma. When stratified by EBV-EA antibody titre, risk of NHL associated with total PCB concentration above the median was 5.2 (95% CI, 1.9–14) among EBV-EA-positive subjects, and ranged from 3.0 to 5.0 for the above-mentioned PCB subgroups; risk for diffuse large B-cell lymphoma ranged from 3.8 to 7.0 by PCB subgroup (all statistically significant), and was 6.2 (95% CI, 1.6–25) for immunotoxic PCBs (Hardell *et al.*, 2009).

A case–control study focused on 54 cases of hairy cell leukaemia [a rare subtype of NHL] identified in the Swedish Cancer registry, and 54 controls drawn from the national population registry, matched to cases by age, sex, and county (Nordström *et al.*, 2000). Concentrations of 36 PCBs were measured in plasma. Overall, risk was not elevated for total PCB concentration greater than the median value (OR, 0.8; 95% CI, 0.3–1.9). When stratifying by EBV-EA antibody titre, the odds ratio for exposure above the median of values was 4.4 (95% CI, 1.2–18.5; 13 cases) for total PCBs and 11.3 (95% CI, 2.3–73.1; 15 cases) for immunotoxic PCBs among subjects with EBV-EA titres ≥ 40 (Nordström *et al.*, 2000). [The Working Group highlighted some methodological concerns about this group of studies, including poor precision, recruitment of cases and controls at different times, some with PCB measurements in adipose tissue and others with measurements in plasma.]

The largest case–control study of PCB body burden in relation to risk of NHL was conducted in Canada (Spinelli *et al.*, 2007). Lipid-adjusted concentrations of 14 PCB congeners were measured in pretreatment samples of plasma from

422 cases of NHL and 460 population controls, frequency-matched to cases by 5-year age-groups, sex, and residence. Odds ratios were adjusted for age, sex, education, BMI, ethnicity, farming, and family history of NHL. Risk of NHL was found to be highest in the highest quartile of the sum of dioxin-like PCBs (OR, 2.40; 95% CI, 1.53–3.77) and of non-dioxin-like congeners (OR, 2.18; 95% CI, 1.41–3.38). Individual congeners showing a significant excess risk in the top quartile of plasma concentration included PCB-118 and PCB-156, among the dioxin-like PCBs, and PCB-138, PCB-153, PCB-170, PCB-180, and PCB-187, among the non-dioxin-like PCBs. The observed associations were consistent across the four NHL subtypes examined, including DLBCL, follicular lymphoma, T-cell lymphoma, and other B-cell lymphomas (Spinelli *et al.*, 2007). [This was one of the largest studies of NHL and PCBs, and accounted for relevant confounders. The Working Group judged it to be a high-quality study, which was notable for providing results for individual congeners and lymphoma subtypes. While the participation rate for controls was less than 50%, the Working Group noted that this was typical of the available case–control studies and that potential confounding factors, including education, were comparable between cases and controls despite differences in participation. The most consistent associations were seen for follicular lymphoma and exposure to dioxin-like PCBs.]

A multicentre European study of NHL included 174 cases and 203 controls from France, Germany, and Spain (Cocco *et al.*, 2008). Patients admitted to the same hospital as the cases for non-cancer diseases not related to known risk factors for NHL were selected as controls in France and Spain; controls in Germany were a random sample of the general population. Concentrations of nine PCB congeners were measured in plasma, and risk estimates were adjusted by age (continuous), sex, education, and centre. Risk of NHL did not increase by quartile of plasma concentration of total PCBs, or specific congeners, or the functional PCB congener groups as defined by Hansen (Hansen, 1998). When exploring risk by lymphoma subtype, a nonsignificant increase was observed for chronic lymphocytic leukaemia in the top quartile of concentration of immunotoxic PCBs and BRCA1-inhibiting PCBs, with no indication of an increasing trend, or of an association with specific PCB congeners. No association was observed with risk of diffuse large B-cell lymphoma. However, risk of chronic lymphocytic leukaemia associated with plasma concentrations of immunotoxic PCBs above the median showed a threefold increase (OR, 3.2; 95% CI, 0.9–11.5), increasing to sixfold (OR, 6.1; 95% CI, 1.0–37.8) in the upper quartile, in subgroup analyses of the German and French subgroups combined, but not in the Spanish subgroup; a significant heterogeneity by country was observed for risk of chronic lymphocytic leukaemia associated with immunotoxic PCBs, but not for the sum of total PCBs. [The Working Group judged this international study to be high in quality; the classification of lymphoma was particularly meticulous. Although the overall results were null, the association of immunotoxic PCBs with chronic lymphocytic leukaemia in two of the three centres is noteworthy. The heterogeneity between countries may have been a result of differences in PCB exposure or distribution of confounding factors.]

Pretreatment plasma samples were available in a subset of 100 cases with a histologically confirmed diagnosis of NHL and 100 controls out of the 1321 cases and 1057 general population controls who participated in a case–control study on NHL conducted by the United States National Cancer Institute in 1998–2000 in four areas with population-based cancer registries (Iowa, Los Angeles, CA, Detroit, MI, and Seattle, WA) (De Roos *et al.*, 2005). Concentrations of 36 non-coplanar and 4 coplanar congeners were measured in plasma. Risk of NHL overall and of its major subtypes was analysed in relation

to 28 PCB congeners detected in at least 30% of samples. Values below the detection limit were estimated by multiple imputation. Odds ratios were adjusted for the matching factors, age, sex, study site, and date of blood draw. Other potential confounders were tested, including education, race, BMI, and family history of NHL, but no confounding was observed. The results showed significant upward trends in risk of NHL with increasing quartiles of plasma concentration of the subgroup of highly chlorinated PCB congeners (test for trend, $P = 0.04$), which included PCB-156, PCB-180, and PCB-194. An increase of 10 TEQ pg/g lipid was associated with a 35% excess risk of NHL (95% CI, 1.02–1.79). Some associations were stronger among the 14 cases of DLBCL than the 25 cases of follicular lymphoma, both in men and women, and trends by exposure quartiles became significant for follicular lymphoma for PCB-180 and PCB-187 (De Roos *et al.*, 2005). [Despite the extensive analysis, this was a relatively small study, with wide confidence intervals.]

Colt *et al.* (2009) used the same data set to explore the interaction between common variants in genes implicated in the immune and inflammatory response and PCB-180, (the non-dioxin like PCB that showed the strongest association between NHL and levels measured in plasma (100 cases and 100 controls) and carpet dust (682 cases and 513 controls) in the analysis by De Roos *et al.* (2005). Sixty-one single nucleotide polymorphisms in 36 proinflammatory and other immunoregulatory genes were analysed in samples of blood or buccal cells. Relative risk estimates were adjusted for sex, age, race, education, and study centre. The concentration of PCB-180 in plasma was associated with increased risk of NHL (OR, 8.3%; 95% CI, 1.9–14.6% per 10% increment), but the concentration in carpet dust was not (OR, 0.7%; 95% CI, 0.0–1.3% per 10% increment). Significant increases in risk of NHL were observed for PCB-180 in both plasma and carpet dust and for *IFNG* (C–1615T) TT, *IL4* (5′-UTR, Ex1-168C>T) CC, *IL16* (3′-UTR, Ex22-871A>G) AA, *IL8* (T–251A) TT, and *IL10* (A–1082G) AG/GG genotypes (Colt *et al.*, 2009).

Another analysis was conducted on the same data set to explore the interaction between status of HLA-DRB1*01:01 class II leukocyte surface antigen and of the extended ancestral haplotype (AH) 8.1 (HLA-A*01-B*08-DR*03-TNF-308A) and blood concentrations of PCB-180 above the median in the control group. Risk of NHL overall was elevated among study subjects lacking the HLA-DRB1*01:01 allele or the AH 8.1 allele (OR, 3.93; 95% CI, 1.49–10.35). No significant increase in risk was observed with PCB-180 in carpet dust or for DLBCL or follicular lymphoma (Wang *et al.*, 2011). [These related studies were well conducted, but the subgroup analyses were based on small numbers.]

2.3.2 Cancer of the breast

See Table 2.10

(a) Smaller studies

Case–control studies of cancer of the breast with 100 or fewer cases, most published before 2000, are reviewed here briefly and are not presented in the table. Most of these studies did not present risk estimates according to PCB concentrations.

One of the earliest studies looked at PCB concentrations in samples of breast adipose tissue from 14 living and 18 deceased patients with cancer of the breast, 21 similar samples from non-cancer patients, and samples of adipose tissue from 35 non-cancer autopsies, and found no significant differences (Unger *et al.*, 1984).

In another study, mean concentrations of PCBs in the breast tissue of 20 women with cancer of the breast were significantly higher ($P = 0.02$) than in 20 women with benign breast disease, and the association persisted after controlling for age, smoking, and BMI (Falck *et al.*, 1992).

Table 2.10 Case-control studies on cancer of the breast and exposure to PCBs

Reference, study location and period	Total No. cases Total No. controls	Control source (hospital, population)	Exposure assessment	Exposure categories	Exposed cases	OR (95% CI)	Covariates Comments
Recio-Vega *et al.* (2011), Comarca Lagunera, Mexico	70 70	Hospital-based: 70 women with biopsies negative for malignancy, from the same hospital	Questionnaire; serum concentrations of 20 PCB congeners[a] measured by GC	Total PCBs	NR	1.09 (1.02–1.16)	Age, age at menarche, lactation, menopausal status, BMI, family history of breast cancer [The Working Group was not clear on how analysis was performed to obtain risk estimates.] PCb groups according to Wolff & Toniolo (1995)

BMI, body mass index; CI, confidence interval; ER, estrogen receptor; GC, gas chromatography; HRT, hormone replacement therapy; Ile, isoleucine; JEM, job-exposure matrix; LOD, limit of detection; NR, not reported; OR, odds ratio; PCB, polychlorinated biphenyl; PCR-RFLP, polymerase chain reaction–restriction fragment length polymorphism; PR, progesterone receptor; ref., reference; TEQ, toxic equivalent; Val, valine; vs, versus

In a study in Quebec City, Canada, in 17 women with cancer of the breast and 17 controls (Dewailly *et al.*, 1994), the concentration of PCB-99 was higher in the breast adipose tissue of women with ER-positive (ER+) infiltrating adenocarcinoma than in controls, while there were no significant differences for ER– women with cancer of the breast compared with controls, or for other PCB congeners or total PCBs.

In a study in Sweden, PCB concentrations were measured in non-tumour breast adipose tissue of 43 women with breast cancer and 35 controls (Liljegren *et al.*, 1998). Odds ratios adjusted for age and parity showed no association with concentrations of total PCB congeners in all subjects. However, among the subgroup of women with ER+ tumours, increased risk was observed for PCB-77 (OR, 33; 95% CI, 1.8–588) and PCB-126 [odds ratio not calculated as there were no unexposed cases].

In Hesse, Germany, concentrations of 12 PCB congeners in breast tissue from 45 women with cancer of the breast were compared with those in breast tissue from 20 women with benign breast disease: the average concentration of PCB-118 was significantly higher in the cases, with no statistical difference for other congeners (Güttes *et al.*, 1998).

A case–control study in eastern Slovakia included 24 cases of cancer of the breast diagnosed between 1997 and 1999 and 88 population controls, and measurements were made of 15 PCBs in serum (Pavuk *et al.*, 2003). Median concentrations of total PCBs were slightly higher among controls, and although odds ratios were less than unity, no finding was statistically significant.

In two reports of studies of 100 cases of cancer of the breast and 100 surgical controls in Belgium (Charlier *et al.*, 2003), concentrations of PCB-101 and PCB-153 were significantly higher for cases than controls. A second study of 60 cases and controls by the same authors reported an association only for PCB-153 (OR, 1.8; 95% CI, 1.4–2.5) after adjusting for age and reproductive risk factors (Charlier *et al.*, 2004). [It was not clear whether the same population was studied in both articles.]

In a case–control study in Mexico, 70 cases of cancer of the breast were compared with 70 hospital controls, and blood samples were taken for measurement of 20 PCB congeners (Recio-Vega *et al.*, 2011). An increased risk of cancer of the breast was apparent for total PCBs (OR, 1.09; 95% CI, 1.02–1.16) and for the exposure groups 2b (OR, 1.90; 95% CI, 1.25–2.88), 3 (OR, 1.81; 95% CI, 1.08–3.04), and 4 (OR, 1.57; 95% CI, 1.20–2.07) defined according to Wolff & Toniolo (1995). Elevated odds ratios were reported for several PCB congeners (PCB-118, PCB-128, PCB-138, PCB-170, PCB-180, PCB-187, PCB-195, PCB-206 and PCB-209) and risks were generally higher in postmenopausal women. [Although this was a small study, several increased risks were reported. However, the analytical approach was unclear to the Working Group and the age distribution was notably different in cases and controls, suggesting potential for residual confounding by age.]

Using a registry of banked serum collected between 1981 and 1987 from 63 Alaskan native women who subsequently developed cancer of the breast and 63 age-matched cancer-free women, analyses adjusting for ethnicity, family history of cancer of the breast, and parity showed no association with PCB exposure (Rubin *et al.*, 2006). In a study in Greenland of 31 cases of cancer of the breast and 115 controls, all of Inuit descent, some evidence of higher serum concentrations of PCBs was found for patients with cancer of the breast compared with controls; however, the odds ratios for total PCBs did not demonstrate any association (Bonefeld-Jørgensen *et al.*, 2011). [The populations included in these studies were of special interest due to their documented high exposures to PCBs.]

(b) *Larger studies of PCB concentrations in blood*

In a case–control study in western New York State, USA, 154 postmenopausal women with incident cancer of the breast and 192 postmenopausal community controls were compared in terms of serum concentrations of 73 detected congeners (Moysich *et al.*, 1998). No association with total PCBs, moderately chlorinated PCBs or highly chlorinated PCBs was found, but increased risk was apparent for less chlorinated PCBs above the detection limit (OR, 1.66; 95% CI, 1.07–2.88 for the combined second and third tertiles); among parous women who had never lactated the magnitude of risk was higher in association with total PCBs (OR, 2.87; 95% CI, 1.01–7.29) and moderately chlorinated PCBs (OR, 3.57; 95% CI, 1.10–8.60). In a subsequent study on PCBs and *CYP1A1* polymorphism (found to be induced by PCBs in experimental studies, see Section 4), no association with *CYP1A1* genotype was found among women with a low PCB body burden; among women with a PCB burden above the median for the control group, an increased risk of cancer of the breast was observed when at least one valine allele was present (OR, 2.93; 95% CI, 1.18–7.45) when compared with women who were homozygous for the isoleucine allele (Moysich *et al.*, 1999b). Adjustment for serum lipids and BMI did not affect the magnitude of this association. [Although not large, this study was rigorous in terms of design and implementation.]

Among patients of several ethnic groups in a hospital-based case–control study in New York City, USA, 175 patients with cancer of the breast and 355 control patients were frequency-matched by age and race/ethnicity (Wolff *et al.*, 2000b). Highly chlorinated and less chlorinated biphenyls and other chlorinated compounds were measured in serum, and the tumour markers ER, progesterone receptor (PR), *p53*, and erbB-2 were assessed. Concentration of PCBs was not associated with risk of cancer of the breast. Risk of cancer of the breast was not examined with respect to tumour stage or markers, but PCB concentrations did not differ according to these factors. [This was a high quality study notable for the number of tumour markers investigated, but the analysis focused largely on exposure markers, rather than exposure–disease associations.]

In a population-based case–control study of cancer of the breast in African-American and white women in North Carolina, USA, 748 cases and 659 controls were enrolled (Millikan *et al.*, 2000). Lipid-adjusted concentrations of 35 PCB congeners were measured in plasma, but detailed analyses were presented only for total PCBs. Odds ratios were adjusted for age and age squared, and additionally for race, menopausal status, BMI, parity/lactation, hormone replacement therapy, and income, depending on the stratification factors. Results were presented in strata of race, parity plus lactation, BMI and history of farming. Risk of cancer of the breast was increased with total PCB exposure among African-American women (third tertile OR, 1.74; 95% CI, 1.00–3.01), but not among white women (third tertile OR, 1.03; 95% CI, 0.68–1.56). This risk was particularly high for African-Americans with BMI > 34.2 (third tertile total PCBs, OR, 4.92; 95% CI, 1.63–14.83). [This was a large, high-quality study, and included African-Americans.]

In the same study population as Millikan *et al.* (2000), Li *et al.* (2005) investigated *CYP1A1* polymorphisms and their interaction with PCB exposure in relation to risk of cancer of the breast among the 612 cases and 599 controls who had provided blood. Results showed no evidence of joint effects between *CYP1A1* M1-containing genotypes and total PCBs for either race. Among white women, statistically significant multiplicative interactions were observed between *CYP1A1* M2-containing genotypes and total PCBs (P = 0.02), but the association between PCBs and cancer of the breast was inverse. A multiplicative interaction was suggested among African-American women between *CYP1A1*

M3-containing genotypes and total PCBs, with an odds ratio of 1.6 (95% CI, 0.8–3.2) for women with total plasma PCB concentrations ≥ 0.430 ng/mL and any *CYP1A1* M3 genotype compared with lower PCB concentration and no M3 genotype (*P* for interaction = 0.10). [This large study was able to assess interactions with *CYP1A1*.]

In a case–control study conducted in 1994–7 in Quebec City, Canada, plasma concentrations of 14 PCB congeners were measured in 314 women with cancer of the breast and 523 controls (219 hospital controls, 304 population controls) (Demers *et al.*, 2002). Analyses in relation to cancer of the breast excluded five congeners that were detected in < 70% of the women. The remaining PCB congeners were correlated (Pearson correlation coefficients, 0.29 to 0.96). Risk of cancer of the breast was associated with the highest quartile of concentration of PCB-118 (OR, 1.60; 95% CI, 1.01–2.53) and PCB-156 (OR, 1.80; 95% CI, 1.11–2.94). Among the subgroup of premenopausal women, the odds ratio for the highest quartile of concentration of PCB-118 was 2.87 (95% CI, 1.13–7.31), and for PCB-156 it was 2.90 (95% CI, 1.18–7.15). No significant increase in risk was seen in postmenopausal women. When PCB-105, PCB-118 and PCB-156 were grouped, higher concentration was associated with increased risk of cancer of the breast (OR, 2.02; 95% CI, 1.24–3.28), but the PCBs that were the most abundant (PCB-138, PCB-153 and PCB-180) were not associated with risk of cancer of the breast. An earlier publication from this study investigated associations between organochlorine compounds and cancer of the breast, specifically in relation to axillary-lymph-node involvement and tumour size (Demers *et al.*, 2000). PCB-153 was selected as a surrogate for all PCB congeners because it was the most abundant in plasma samples and was strongly correlated with other prevalent congeners ($r \geq 0.72$; $P < 0.0001$). The relative risk of having a tumour size ≥ 2 cm was increased, but not significantly, with increasing plasma concentration of PCB-153. However, a higher concentration of PCB-153 was significantly associated with increased risk among those with axillary lymph-node involvement (OR, 2.12; 95% CI, 1.05–4.30, adjusted for confounders) and when tumour size > 2 cm and node involvement were considered together, (OR, 3.51; 95% CI, 1.41–8.73), with an exposure–response trend. [This was a well-designed and well-implemented study with two control groups and stratification for menopausal status.]

In a large population-based case–control study of environmental exposures and cancer of the breast conducted in 1996–7 on Long Island, NY, USA, serum concentrations of 24 PCB congeners were measured for 646 cases and 429 controls, with results presented for the four most commonly occurring congeners (PCB-118, PCB-138, PCB-153 and PCB-180) (Gammon *et al.*, 2002). There was no association between cancer of the breast and the sum concentration of the four PCBs, or any specific congener, and there was no effect of lactation, menopausal status, stage of disease, or hormone receptor status. [This was a large, well-designed and well-implemented study.]

In a population-based case–control study of African-American women, serum concentrations of PCBs [congeners not specified] were measured in 355 cases and 327 controls (Gatto *et al.*, 2007). Risk of cancer of the breast was not associated with total PCBs (OR comparing highest with lowest quintile, 1.01; 95% CI, 0.64–1.63), and BMI, parity, breastfeeding, and menopausal status did not modify the measures of effect. PCBs were not associated with an increase in the risk of any subtype of cancer of the breast as defined by PR, ER, *p53*, or HER-2/*neu* status. [Statistical power was limited for subgroup analyses.]

In a hospital-based case–control study of cancer of the breast in Nagano, Japan, including 403 matched pairs collected from 2001 to 2005, serum concentrations of total PCBs were associated with decreased risk of cancer of the

breast for the highest versus lowest quartile of concentration of total PCBs (OR, 0.33; 95% CI, 0.14–0.78) (Itoh *et al.*, 2009). For the specific congeners PCB-153 and PCB-180, the odds ratios were 0.40 (95% CI, 0.18–0.91) and 0.29 (95% CI, 0.13–0.66), respectively. The trend in the inverse relationship persisted when results were stratified by hormone-receptor and menopausal status. [The Working Group was not able to explain the inverse associations reported in this study.]

(c) *Larger studies of PCB concentrations in blood and breast adipose tissue*

Five publications from a research group in Connecticut, USA, were informative, although their potential overlap was not clear. In 1994–1997, 304 cases of cancer of the breast and 186 controls aged 40–79 years were recruited and breast adipose tissue was analysed for nine PCB congeners (PCB-74, PCB-118, PCB-138, PCB-153, PCB-156, PCB-170, PCB-180, PCB-183 and PCB-187) (Zheng *et al.*, 2000a). Age- and lipid-adjusted risk estimates were null in relation to total PCBs, PCB groups, and any of the congeners. Stratification by type of breast disease, menopausal status, parity, lactation, and body size showed null associations with concentrations of PCBs. From the same study population, Holford *et al.* (2000) calculated risk in relation to both linear logistic and logistic ridge regression analyses for nine PCB congeners by incremental (10 ng/g) changes in exposure: PCB-153 and PCB-156 were associated with decreased risk and PCB-180 and PCB-183 were associated with increased risk of cancer of the breast. In analyses using ridge regression and adjusting for covariates, no congeners remained associated with cancer of the breast. In another case–control study from this research group, subjects were recruited in 1995–1997 (overlap in years of study with Zheng *et al.*, 2000a): 475 incident cases of cancer of the breast were included, and 502 controls were randomly selected from the population or from patients with newly diagnosed benign breast disease at the same hospital (Zheng *et al.*, 2000b). Serum concentrations of nine PCB congeners were determined. After adjustment for confounding factors, all odds ratios were null. A related study focused on the potential interaction between CYP1A1 and lipid-adjusted serum concentrations of PCBs on risk of cancer of the breast among Caucasian women recruited in 1999–2002, with 374 cases and 406 controls (Zhang *et al.*, 2004). The odds ratio for high exposure (> 610 ng/g) to PCBs was 1.2 (95% CI, 0.9–1.6). With respect to *CYP1A1* genotype, the risks associated with higher serum concentration of total PCBs was highest for carriers of the *m2* variant genotype both among all women combined (OR, 3.6; 95% CI, 1.5–8.2), and in postmenopausal women (OR, 4.3; 95% CI, 1.6–12.0). No significant association was reported for *CYP1A1 m1* or *m4* genotypes or among premenopausal women. Finally, in another publication on a subset of 266 cases of cancer of the breast and 347 controls with benign breast disease, there was no association for total subjects, adjusted for standard risk factors, between cancer of the breast by joint ER/PR status and serum concentrations of total PCBs and adipose-tissue concentrations of nine PCB congeners (Rusiecki *et al.*, 2004). However, among postmenopausal women, increased risk of cancer of the breast was seen in relation to increased concentrations of PCB-183 among women with ER+PR+ tumours (third versus first tertile, OR, 2.4; 95% CI, 1.0–6.0; *P* for trend = 0.03). [While there appeared to be overlap between this group of studies from Connecticut, the extent of the overlap was difficult to determine, therefore the independence of the findings was not known. Controls were drawn from a mix of hospital and population sources, and the impact of this selection method was difficult to gauge. The large number of subgroup analyses, particularly in the study by Rusiecki *et al.* (2004), which presented 80 odds ratios, increased the probability of chance findings.]

(d) Larger studies of PCB concentrations in adipose tissue

On Long Island, New York, USA, concentrations of 14 PCB congeners in adipose tissue did not differ for 232 women with cancer of the breast and 323 hospital controls with benign breast disease or non-breast-related conditions, after adjustment for age, race, and BMI (Stellman *et al.*, 2000). No increase in risk was observed for total PCBs, but congeners PCB-156 and PCB-183 were associated with significantly increased risk (OR, 1.9; 95% CI, 1.1–3.0 for the second tertile of exposure distribution for PCB-156; and OR, 2.0; 95% 1.2–3.4 for the highest tertile of PCB-183). No other congener was associated with risk of cancer of the breast, and no clear difference in risk was seen for ER+ and ER– tumours. [This was a large, well-designed study, but results were only presented for total PCBs and two congeners.]

In a case–control study in Kingston and Toronto, Ontario, Canada, noncancerous breast adipose tissue collected before treatment from 217 incident cases of cancer of the breast and 213 controls undergoing biopsy was analysed for 14 PCB congeners (Aronson *et al.*, 2000). PCB-105 and PCB-118 were associated consistently with risk of cancer of the breast after adjusting for other factors (OR, 3.17; 95% CI, 1.51–6.68; and OR, 2.31; 95% CI, 1.11–4.78, respectively, for the fourth versus first quartile of the exposure distribution) and these effects increased monotonically. PCB-138 was also associated consistently with increased risk, but the odds ratios were imprecise. Stronger associations were apparent among premenopausal women (PCB-105: OR, 3.91; 95% CI, 1.73–8.86; and PCB-118: OR, 2.85; 95% CI, 1.24–6.52, for the highest exposure category). Among postmenopausal women, risks associated with PCB-170 and PCB-180 were also elevated in the second of three exposure groups (OR, 3.27; 95% CI, 1.44–7.44; and OR, 2.43; 95% CI, 1.09–5.43, respectively), but declined below significance in the highest group (ORs 1.63 and 1.77, respectively). No other PCB congener was significantly associated with risk. Although the odds ratios did not differ significantly by subtype of cancer, the odds ratios for total PCBs were higher for ER– than for ER+ cancer of the breast (Woolcott *et al.*, 2001). Investigation of specific genotype–PCB interactions among 68 cases and 52 controls with blood samples in this study showed increased risk of cancer of the breast for *CYP1A1* M1 wildtype homozygotes with high exposure to PCB-105 (OR, 3.20; 95% CI, 1.14–8.98) (McCready *et al.*, 2004). [This was a large, well-designed study.]

(e) Exposure estimates from occupational or dietary histories

A few case–control studies have estimated PCB exposures from occupational or dietary histories.

A population-based case–control study in Massachusetts, USA, included 261 incident cases of cancer of the breast diagnosed between 1983 and 1986 and 753 controls. The subjects were interviewed to ascertain all full-time jobs held since age 18 years. Probable exposure to PCBs was associated with non-significant increases in the risk of cancer of the breast (adjusted OR, 3.2; 95% CI, 0.8–12.2; five exposed cases and six exposed controls) (Aschengrau *et al.*, 1998). [The Working Group noted imprecise findings.]

Consumption of fish from the Great Lakes as a source of exposure to PCBs was investigated as a potential risk factor for cancer of the breast in a population-based case–control study in Wisconsin, USA (McElroy *et al.*, 2004). There were 1481 cases aged 20–69 years, diagnosed in 1998–2000 in the Wisconsin Cancer Reporting System, and 1301 controls of similar age were randomly selected from licensed drivers and Medicare lists; telephone interviews were used to obtain information on consumption of all sport-caught (Great Lakes and other lakes) fish and risk factors for cancer of the breast. After adjustment for risk factors, including age, education, weight,

alcohol consumption, reproductive history, and family history of cancer of the breast, no association was found between risk of cancer of the breast and recent consumption of sport-caught fish (OR, 1.00; 95% CI, 0.86–1.17), recent consumption of fish from the Great Lakes (OR, 1.06; 95% CI, 0.84–1.33), or the number of fish meals per year. Menopausal status appeared to be an effect modifier, with recent consumption of fish from the Great Lakes not associated with postmenopausal cancer of the breast (OR, 0.78; 95% CI, 0.57–1.07), but with premenopausal breast cancer (OR, 1.70; 95% CI, 1.16–2.50). [This was a large study with exposure assessment that used consumption of sport fish as a proxy for PCB exposure, but did not use biomarkers.]

(f) Combined analysis of five studies in the USA

The results of five case–control studies in the north-east USA conducted before 2000 (of which three are nested in cohort studies) (Moysich *et al.*, 1998; Helzlsouer *et al.*, 1999; Laden *et al.*, 2001a, b and Hunter *et al.*, 1997; Zheng *et al.*, 2000a, b; Wolff *et al.*, 2000b) and in which plasma or serum concentrations of PCBs were measured have been combined into an analysis of 1400 cases and 1642 controls using a standardized approach to confounder and effect-modification assessment, and a random-effects model to estimate associations (Laden *et al.*, 2001b). For women in the fifth quintile of lipid-adjusted values compared with those in the first quintile, the multivariate pooled odds ratio for cancer of the breast associated with the sum of PCBs (PCB-118, PCB-138, PCB-153 and PCB-180) was 0.94 (95% CI, 0.74–1.21). No consistent increase in risk was observed in subgroups defined by parity or lactation. [This combined analysis focused on the most prevalent PCBs that were analysed in all five studies; while this enhanced precision for the overall relationship, it did not show associations for specific PCB congeners and PCB subgroups. The Working Group noted that several informative studies were published after this combined analysis.]

2.3.3 Cancer of the prostate

Several epidemiological studies have investigated possible associations between cancer of the prostate and exposure to PCBs. These studies differed in study design (i.e. case–control studies, nested case–control studies) and in the assessment of PCBs (i.e. job-exposure matrices, measurement of PCB concentrations in blood or adipose tissue).

Seidler *et al.* (1998) described the results of a case-referent study including 192 patients with cancer of the prostate and 210 controls from medical practices or clinic in Germany. Occupational exposure to PCBs was estimated using a British job-exposure matrix (Pannett *et al.*, 1985). Most subjects had no or low exposure to PCBs and no association between exposure and risk of cancer of the prostate was reported. [Due to the relative low participation rate among controls (55%), selection bias could not be excluded. Furthermore, the validity of the job-exposure matrix was unknown and significant exposure misclassification could not be ruled out.]

Ritchie *et al.* (2003, 2005) conducted a hospital-based case–control study in Iowa, USA, in which 30 PCB congeners were measured in serum samples from 58 patients with cancer of the prostate and 99 age-matched controls. Odds ratios were elevated for total PCBs, and for PCB-153, and PCB-180. A monotonic, not statistically significant, exposure–response trend was observed for total PCBs. For PCB-180, the odds ratio was significantly increased (OR, 3.13; 95% CI, 1.33–7.34) only in the middle (but not the highest) category of exposure. [This study was small with multiple comparisons.]

In a population-based case–control study in Sweden, Hardell *et al.* (2006a) compared

concentrations of 37 PCB congeners in samples of fat tissue from 58 cases of cancer of the prostate and 20 controls with benign prostate hyperplasia. The odds ratio for the sum of PCBs and cancer of the prostate was 1.21 (95% CI, 0.42–3.50) in all men. PCB-153 was associated with an increased risk of cancer of the prostate (OR, 3.15; 95% CI, 1.04–9.54). Stronger associations were observed in men with prostate-specific antigen (PSA) > 16.5 ng/mL; the odds ratio was 1.91 (95% CI, 0.55–6.55) for total PCBs, and risks for enzyme and phenobarbital-inducing PCBs (Wolff *et al.*, 1997) and for less chlorinated PCBs (Moysich *et al.*, 1999a) were significantly increased in this subgroup of men. [This study was small and involved multiple comparisons.]

Aronson *et al.* (2010) conducted a case–control study among urology patients in Ontario, Canada. Concentrations of 14 PCB congeners were measured in serum of 79 men with incident cancer of the prostate and 329 age-matched controls. No association was observed between concentrations of individual PCB congeners or the sum of PCBs, and the risk of prostate cancer. [As both cases and controls underwent the same diagnostic procedures and were screened by PSA and digital rectal examination, selection bias was unlikely in this study].

2.3.4 Melanoma

(a) Cutaneous malignant melanoma

See Table 2.11

Gallagher *et al.* (2011) conducted a case–control study of 80 patients with malignant melanoma of the skin and 310 controls. The cases were part of a larger case–control study and were originally recruited to evaluate the effect of exposure to ultraviolet (UV) light and gene variants on risk of melanoma, and the controls were recruited using population-based registries. Lipid-adjusted plasma concentrations of 14 PCB congeners were determined and data were reported for 8, as well as for total PCBs, and dioxin-like and non-dioxin-like PCBs. Statistically significant associations with malignant melanoma were observed for the highest compared with the lowest quartile for: total PCBs (OR, 6.02; 95% CI, 2.0–18.17); summed non-dioxin-like PCBs (OR, 7.02; 95% CI, 2.30 –21.43); summed dioxin-like PCBs (OR, 2.84; 1.01–7.97), and all of the individual PCB congeners examined (PCB-118, PCB-138, PCB-153, PCB-156, PCB-170, PCB-180, PCB-183 and PCB-187). [The Working Group considered that, in light of its appropriate design and control of relevant potential confounders, this was a high-quality study, despite the relatively small sample size and being described as "preliminary" by the authors. The positive associations for all the individual PCB congeners may have been a result of correlations among congeners. Multiple comparisons were not formally addressed, but it is likely that adjustment for multiple comparisons would not change the interpretation of the results.]

(b) Uveal melanoma

See Table 2.11

In a multicentric case–control study in nine European countries, Behrens *et al.* (2010) investigated the association between risk of uveal melanoma and exposure to PCBs. The 293 men and women with uveal melanoma were frequency-matched to 3198 population and hospital controls by country, age, and sex. Exposure to transformer oils was assessed by questionnaire, with exposures to PCBs classified as "potential" or "confirmed," depending on whether subjects reported exposure to a named brand of oil with known PCB content. Analyses were adjusted for age, country, eye colour, and history of ocular damage from ultraviolet light. Only men reported exposure to transformer/capacitor oils. The odds ratio for any exposure was 2.74 (99.3% CI, 1.07–7.02), and was similar in magnitude for men with more than 10 years of exposure and for "confirmed" exposure. For exposure to Pyralene (the most frequently reported PCB-containing

Table 2.11 Case–control studies on melanoma and exposure to PCBs

Uveal melanoma							
Behrens *et al.* (2010), Denmark, France, Germany, Italy, Latvia, Portugal, Sweden, Spain, UK Jan 1994–Dec 1997	293 3198	Hospital and population	Questionnaire on occupational exposure	Exposure to oils potentially containing PCBs			Country, age, ocular damage due to UV, eye colour, exposure to high-voltage installations ORs were Bonferroni-corrected for seven independent tests to control for multiple comparisons, thus all CI are 99.3%. Response rates: cases, 84%; hospital, 84%; population controls, 61% Only men were exposed to oils
				Never exposed	150	1.00	
				Ever exposed	6	2.74 (0.72–10.37)	
				Duration > 10 years	2	2.62 (0.29–24.06)	
				"Confirmed" exposure to PCB oil	4	2.61 (0.54–12.63)	
				Exposure to Pyralene	4	6.43 (1.17–35.30)	

[a] The 14 PCB congeners were PCBs 28, 52, 99, 101, 105, 118, 128, 138, 153, 156, 170, 180, 183, and 187.

CI, confidence intervals; DL-PCB, dioxin-like PCB; NDL-PCB, non-dioxin-like PCB; OR, odds ratio; PCB, polychlorinated biphenyl; UK, United Kingdom; UV, ultraviolet

oil), the odds ratio was 6.43 (99.3% CI, 1.17–35.30; four cases). [This study was notable in being the only large study of a rare cancer. Multiple comparisons were addressed via adjusted 99.3% confidence intervals, but exposure was rare and estimates were imprecise.]

2.3.5 Other cancers

(a) Urothelial cancer

Steineck *et al.* (1990) carried out a population-based case-referent study of urothelial cancer in men in Stockholm, Sweden. Occupational exposures to PCBs and several other agents were assigned by an industrial hygienist. The adjusted odds ratio for estimated exposure to PCBs was 3.3 (95% CI, 0.6–18.4). [The precision of this study was quite limited and the definition of the cancer sites was broad.]

(b) Cancer of the testis

Hardell *et al.* (2003) analysed 38 PCB congeners in blood samples collected from 61 incident cases of cancer of the testis and 58 age-matched controls from the Swedish population registry. No association between cancer of the testis and the sum of PCB concentrations in blood was found. Mothers of 44 cases and 45 controls also provided blood samples; significantly higher PCB concentrations were found for mothers of cases compared with mothers of controls (OR, 3.8; 95% CI, 1.4–10). A difference in the sum of PCBs between mothers of cases and mothers of controls was also reported in two subsequent publications by the same authors (Hardell *et al.*, 2004, 2006b). [Due to the timing of blood collection of the mothers, which was decades after the cases' births, the interpretation of these results was difficult. PCB concentrations in women may be affected by weight changes, child bearing, lactation, and subsequent exposure. Thus it could not be assumed that the concentrations measured in women at the time of the study were representative of their sons' exposures in utero.]

(c) Cancer of the lung

Recio-Vega *et al.* (2012) investigated the association between PCB concentrations, *CYP1A1* polymorphisms and the risk of cancer of the lung in a case–control study in northern Mexico including 43 cases of cancer of the lung and 86 controls without cancer who were recruited from two hospitals. Information including history of exposure to PCBs was collected through in-person interview and 20 PCB congeners were measured in serum. Odds ratios were adjusted for age, agricultural occupation, and tobacco smoking. There was a significant association between PCB-18 and cancer of the lung (OR, 1.13; 95% CI, 1.04–1.38). Odds ratios for PCB-52, PCB-118, and PCB-170 were similar in magnitude, but did not reach statistical significance, while odds ratios for other congeners were close to unity. *CYP1A1* polymorphism was not associated with serum concentrations of total PCBs. [The Working Group noted that this study provided information about less chlorinated PCBs, which are rarely measured; however, the etiological relevance of measurements of PCBs of short half-life was questionable. In addition, the methods used for subject recruitment and for statistical analysis were not clearly described, and the possibility of residual confounding by age was noted.]

(d) Cancer of the colorectum

Howsam *et al.* (2004) assessed associations between cancer of the colorectum and exposure to PCBs and gene–environment interactions in 132 cases and 76 controls sampled from a larger hospital-based case–control study in Barcelona, Spain. Serum concentrations of PCB-28, PCB-52, PCB-101, PCB-118, PCB-138, PCB-153, and PCB-180 were measured. Point mutations in *K-ras* and *p53* genes and expression of p53 protein were assessed in tumour tissue. PCB-28 and PCB-118 were significantly associated with an increased risk of cancer of the colorectum (ORs, 2.75;

95% CI, 1.29–5.83; and 2.02; 95% CI, 1.00–4.08, respectively), for the more exposed category. A statistically significant exposure–response trend was observed for the mono-*ortho* PCB group that combined PCB-28 and PCB-118 (*P* for trend = 0.004). Odds ratios for the other PCBs were not consistently or significantly increased. No significant interaction of mono-*ortho* PCBs with *p53* or *K-ras* mutations was found. [The use of controls representing several diagnostic groups and control for potential confounding factors were strengths of this study. However, the case definition combining cancers of the colon and rectum may mix diseases with potentially different etiologies.]

(e) Cancer of the pancreas

In a population-based case–control study of cancer of the pancreas in the San Francisco area, USA, Hoppin *et al.* (2000) analysed 11 PCB congeners in serum samples from 108 cases of cancer of the pancreas and 82 controls matched by sex and age-group. Total lipid-adjusted PCB concentrations were estimated using the sum of all congeners. A statistically significant dose–response relationship ($P < 0.001$) was observed for total PCBs, with an odds ratio of 4.2 (95% CI, 1.8–9.4) for ≥ 360 versus < 185 ng/g. Significantly elevated odds ratios were also observed for the highest tertiles of PCB-153 (OR, 3.0; 95% CI, 1.4–6.6) and PCB-180 (OR, 8.4; 95% CI, 3.4–21). Odds ratios remained elevated after adjusting for dichlorodiphenyldichloroethylene (DDE) content, and in a sensitivity analysis of the effects of bioconcentration. [A strength of the study was that the issue of confounding by bioconcentration in fat due to adipose-tissue loss was addressed. Nevertheless, the small number of subjects limited a clear interpretation of the results.]

(f) Cancer of the biliary tract

Ahrens *et al.* (2007) investigated the association between cancer of the extrahepatic biliary tract and occupational exposure to endocrine-disrupting compounds in a European multicentre case–control study of 183 men with histologically confirmed carcinoma of the extrahepatic biliary tract and 1938 matched controls. Self-reported job descriptions were converted to semiquantitative indicators of occupational exposure to 14 types of suspected endocrine-disrupting compounds, including PCBs, hormones, phthalates, and pesticides. Odds ratios were adjusted for age, country, and history of gallstones. The adjusted odds ratio for cancer of the extrahepatic biliary tract and ever-exposure to PCBs was 2.8 (95% CI, 1.3–5.9). When exposure intensity was analysed, the highest odds ratio was observed in the low-intensity category. [These results were based on a small number of exposed cases and trends were inconsistent.]

(g) Childhood cancer

Ward *et al.* (2009) conducted a population-based case–control in California, USA of 184 children aged 0–7 years with acute lymphocytic leukaemia and 212 controls from birth certificates matched by birth date, sex, race, and ethnicity. Concentrations of six PCB congeners in residential carpet dust were used as an exposure indicator. The odds ratio for detection of any PCB in dust was 1.97 (95% CI, 1.22–3.17) and the odds ratio for the highest quartile of total PCBs compared with the lowest was 2.78 (95% CI, 1.41–5.48). Significant exposure–response trends were reported for PCB-118, PCB-138 and PCB-153. [The study was well-designed and the method of exposure assessment used was a strength. The authors were able to rule out confounding by several organochlorine pesticides. The Working Group was unable to replicate the *P* values for trend tests.]

(h) Cancer of the endometrium

Sturgeon *et al.* (1998) conducted a multicentric hospital-based case–control study of cancer of the endometrium in five areas of the USA. Serum concentrations of 27 PCB congeners were measured for 90 individually matched case–control pairs. No associations were observed between elevated serum concentrations of several PCB groups, including total PCBs and potentially estrogenic PCBs, and risk of cancer of the endometrium. [The results did not appear to be affected by selection bias, but precision was limited.]

Weiderpass *et al.* (2000) measured serum concentrations of 10 PCB congeners in a population-based case–control study of 154 cases of cancer of the endometrium and 205 controls in Sweden. After adjustment there was no increase in risk associated with high concentrations of any of the congeners evaluated, and there were no significant trends in risk. [The power of this study was limited due to the small number of subjects. However, selection bias was unlikely, as the main reason for non-participation was the failure of the hospital staff to collect blood samples before surgery.]

Hardell *et al.* (2004) conducted a hospital-based case–control study with 76 cases and 39 controls to evaluate the risk of cancer of the endometrium associated with environmental endocrine disruptors. Concentrations of 37 PCB congeners were measured in adipose tissue. No association was found for the sum of PCBs or for any grouping of PCBs by structure or activity. [The power of this study was limited due to the small number of subjects.]

(i) Cancer of the male breast

Occupational risk factors for cancer of the male breast were investigated in a multicentric study of 104 cases and 1901 controls in eight European countries (Villeneuve *et al.*, 2010). Lifetime work history was obtained by in-person interviews, and potential occupational exposures including to PCBs were assessed using expert judgment. Results were reported for PCBs and dioxins combined, for which the fully-adjusted odds ratio was 1.6 (95% CI, 0.7–3.7). [This study had limited power to detect excess risk.]

3. CANCER IN EXPERIMENTAL ANIMALS

In previous evaluations in 1978, 1979, 1987, and 2012 (IARC, 1978, 1979, 1987, 2012), the Working Group concluded that there was *sufficient evidence* in experimental animals for the carcinogenicity of polychlorinated biphenyls (PCBs). New data have since become available, and these have been taken into account in the present evaluation.

3.1 Oral administration

See Table 3.1 and Table 3.2

3.1.1 Individual PCBs and binary mixtures

The United States National Toxicology Program (NTP) has conducted a series of studies to evaluate the carcinogenicity of some PCB congeners administered alone or as binary mixtures in female Harlan Sprague-Dawley rats treated by gavage.

(a) PCB-126

Rat

Groups of 81 female Harlan Sprague-Dawley rats (age, 8 weeks) were given the dioxin-like congener PCB-126 at a dose of 0 (vehicle control), 30, 100, 175, 300, 550, or 1000 ng/kg body weight (bw) by gavage in corn oil : acetone (99 : 1), 5 days per week, for up to 104 weeks (core study) (Brix *et al.*, 2004; Nyska *et al.*, 2004; Walker *et al.*, 2005; Yoshizawa *et al.*, 2005, 2007, 2009; NTP, 2006a). Ten rats per group were evaluated at 14, 31, or 53 weeks. A stop-exposure group of 50 female rats was given PCB-126 at a dose of 1000 ng/kg bw in corn oil : acetone (99 : 1) by gavage for 30 weeks, then the vehicle only for the remainder of the study. There were treatment-related increases in the incidences of cholangiocarcinoma and hepatocellular adenoma in rats treated with PCB-126 at doses of 300 ng/kg bw or higher, and 550 ng/kg bw or higher, respectively, for up to 104 weeks. There were three hepatocholangiomas in the group at 1000 ng/kg bw, and single incidences of cholangioma in the groups at 550 and 1000 ng/kg bw. [These tumours are rare, and it was uncertain whether they were related to treatment.] There were also statistically significant, dose-related increases in the incidences of a spectrum of non-neoplastic lesions that collectively were diagnosed as toxic hepatopathy. Significant increases in the incidence of cystic keratinizing epithelioma of the lung occurred in rats at 550 ng/kg bw or higher, and non-statistically significant low incidences of squamous cell carcinoma of the lung were also observed at the highest doses in the core-study groups. Gingival squamous cell carcinomas were observed in all exposure groups, and incidence was significantly increased in the group at 1000 ng/kg bw (core study). Adenomas and/or carcinomas were present in the adrenal cortex of rats in most groups, including the stop-exposure group, with a positive trend in the incidence of adenoma or carcinoma (combined) with increasing dose.

Table 3.1 Studies of carcinogenicity in rats exposed to PCBs and related compounds

Strain (sex) Duration Reference	Dosing regimen, Animals/group at start	For each target organ: Incidence and/or multiplicity of tumours	Significance	Comments
Individual PCBs and binary mixtures				
Harlan Sprague-Dawley (F) 104 wk NTP (2006a)	Core study: PCB-126 in corn oil : acetone (99 : 1) by gavage at doses of 0, 30, 100, 175, 300, 550, or 1000 ng/kg bw, 5 days/wk, for 104 wk 81 rats/group Stop-exposure study: PCB-126 at 1000 ng/kg for 30 wk followed by vehicle for the remainder of the study 50/group Interim evaluations: 10 rats per core study group were evaluated at wks 14, 31, and 53	*Liver* Cholangiocarcinoma (includes multiple): 0/53, 0/55, 1/53, 0/53, 5/53, 6/51, 22/53; 0/53, 2/50 (stop-exposure) Multiple: 0/53, 0/55, 0/53, 0/53, 0/53, 4/51, 15/53; 0/53, 0/50 (stop-exposure) Hepatocellular adenoma[a] (includes multiple): 1/53, 2/55, 1/53, 0/53, 2/53, 4/51, 7/53; 1/53, 0/50 (stop-exposure) Multiple: 0/53, 0/55, 0/53, 0/53, 0/53, 0/51, 1/53; 0/53, 0/50 (stop-exposure) Hepatocholangioma[b] (includes multiple): 0/53, 0/55, 0/53, 0/53, 0/53, 0/51, 3/53; 0/53, 0/50 (stop-exposure) Multiple: 0/53, 0/55, 0/53, 0/53, 0/53, 0/51, 1/53; 0/53, 0/50 (stop-exposure) Cholangioma[b]: 0/53, 0/55, 0/53, 0/53, 0/53, 1/51, 1/53; 0/53, 0/50 (stop-exposure) *Lung* Cystic keratinizing epithelioma (includes multiple): 0/53, 0/55, 0/53, 0/53, 1/53, 11/51**, 35/51*; 0/53, 0/50 (stop-exposure) Multiple: 0/53, 0/55, 0/53, 0/53, 0/53, 8/51*, 30/51*; 0/53, 0/50 (stop-exposure) Squamous cell carcinoma: 0/53, 0/55, 0/53, 0/53, 0/53, 1/51, 2/51; 0/53, 0/50 (stop-exposure)	$P < 0.001$ (1000 ng/kg bw) $P < 0.001$ (trend) $P \leq 0.001$ (1000 ng/kg bw) $P = 0.033$ (1000 ng/kg bw) $P < 0.001$ (trend) $P < 0.001$ (trend) NS NS *$P < 0.001$ **$P = 0.002$ $P < 0.001$ (trend) *$P \leq 0.001$ NS	Purity, 99% The overall incidence values are presented, but statistical analyses are based on the poly 3 test used by NTP that takes survival differences into account *Non-neoplastic lesions* Liver: toxic hepatopathy that included hepatocyte hypertrophy and hyperplasia, bile duct and oval cell hyperplasia, nodular hyperplasia, cholangiofibrosis, multinucleated hepatocytes, diffuse fatty change, bile duct cyst, necrosis, pigmentation, inflammation, portal fibrosis Lung: squamous metaplasia, and bronchiolar metaplasia of the alveolar epithelium No tumours were observed at interim evaluations at wk 14 and 31

Sprague-Dawley (M, F) 29 mo Norback & Weltman (1985)	Feed containing Aroclor 1260 (mixed with corn oil) at 100 ppm for 16 mo, then at 50 ppm for an additional 8 mo, and then the control diet for an additional 5 mo. Controls received basal diet with added corn oil for 18 mo, then the basal diet only for 10 mo The medial and left lobes of the liver of 10 rats (2 M and 2 F controls, and 3 M and 3 F PCB-treated rats, for each period) were removed (partial hepatectomy) at 1, 3, 6, 9, 12, 15, and 18 mo Control: 63/group (M, F) Aroclor 1260: 70/group (M, F)	*Liver* Neoplastic nodule: 0/32, 5/46 (M); 1/49, 2/47 (F) Trabecular carcinoma: 0/32, 2/46 (M); 0/49, 19/47 (F) Adenocarcinoma: 0/32, 0/46 (M); 0/32, 24/47 (F) Cholangioma (simple): 2/32, 14/46 (M); 2/49, 21/47 (F) Cholangioma (cystic): 0/32, 2/46 (M); 1/49, 5/47 (F)	NS $P < 0.0001$ (F) $P < 0.0001$ (F) $P = 0.01$ (M) $P < 0.0001$ (F) NS	Purity, NR Some adenocarcinoma-bearing rats also had trabecular carcinoma (not included in the incidence of trabecular carcinoma) PCB-exposed rats developed hepatocellular lesions in the following sequence: centrilobular cell hypertrophy at 1 mo, foci of cell alteration at 3 mo, areas of cell alteration at 6 mo, neoplastic nodules at 12 mo, trabecular carcinoma at 15 mo, and adenocarcinoma at 24 mo

Table 3.1 (continued)

Strain (sex) Duration Reference	Dosing regimen, Animals/group at start	For each target organ: Incidence and/or multiplicity of tumours	Significance	Comments
Wistar (M) Up to 832 days Schaeffer *et al.* (1984), Faroon *et al.* (2001)	Basic diet for 8 wk, then: Group 1: basic diet; 139 rats (controls) Group 2: basic diet supplemented with Clophen A 30 at 100 ppm; 152 rats Group 3: basic diet supplemented with Clophen A 60 at 100 ppm; 141 rats After 801 days, randomly selected rats from all three groups were killed daily up to day 832	Hepatocellular neoplastic nodules: 5/131, 38/130*, 63/126* Hepatocellular carcinoma: 1/131, 4/130, 61/126* Thymoma: 16/131, 4/130, 2/129 Other neoplasms: 88/131, 66/138, 33/129	*$P < 0.05$ *$P < 0.05$ NS NS	Purity of Clophen A 30, 99.1%; purity of Clophen A 60, 99.9% Over the first 800 days on study, total mortality in groups 2 and 3 was significantly lower than in group 1 (controls) Hepatic foci of cellular alteration were observed in all groups, but were more frequent in the treated groups. There was a trend from foci to neoplastic nodules to hepatocellular carcinoma. Other non-neoplastic hepatic lesions observed in control and treated groups included bile duct hyperplasia The results of a re-evaluation of the hepatocellular tumours using contemporary diagnostic criteria and nomenclature were in general consistent with the original evaluation (Moore *et al.*, 1994) Tumour data were reported in six 100-day periods; the data reflected incidences from day 1 until day 832
Sherman (F) 22 mo Kimbrough *et al.* (1975), Moore *et al.* (1994)	Diets containing Aroclor 1260 at 0 or 100 ppm for up to 21 mo 200/group	*Liver* Hepatic neoplastic nodules: 0/173, 144/184 Hepatocellular carcinoma: 1/173, 26/184	$P < 0.0001$ $P < 0.0001$	Purity, NR The incidences of the hepatocellular lesions were re-evaluated by a panel of pathologists using contemporary diagnostic criteria and nomenclature (Moore *et al.*, 1994). Lesions that had been previously diagnosed as neoplastic nodules were now classified as either hepatocellular hyperplasia or hepatocellular adenoma. In general, the results were consistent between the original evaluation and the re-evaluation

(b) PCB-153

Rat

Groups of 80–82 female Harlan Sprague-Dawley rats (age, 8 weeks) were given the di-*ortho*-substituted non-dioxin-like congener PCB-153 (purity, 99%) at a dose of 0 (81 rats; vehicle control), 10, 100, 300, 1000, or 3000 µg/kg bw, in corn oil:acetone (99 : 1) by gavage, 5 days per week, for up to 105 weeks (core study) (Yoshizawa *et al.*, 2005, 2007, 2009; NTP, 2006b). Ten rats per group were evaluated at 14, 31, or 53 weeks. A stop-exposure group of 50 female rats was given PCB-153 at 3000 µg/kg bw corn oil : acetone (99 : 1) by gavage for 30 weeks, and then the vehicle only for the remainder of the study. At 2 years, cholangiomas occurred in two rats at 1000 µg/kg bw and in two rats in the stop-exposure group. A single hepatocellular adenoma was observed in the group at 3000 µg/kg bw. Cholangioma did not occur in the historical vehicle controls (0 out of 371) of the NTP studies. [One factor limiting interpretation of effects in this bioassay was that the highest dose of PCB-153 used (3000 µg/kg bw) was chosen to match the highest dose used in an NTP bioassay with a mixture of PCB-126 and PCB-153 (NTP, 2006c), rather than on the basis of the results of a previous short-term study of toxicity. There was no effect of PCB-153 at 3000 µg/kg bw on survival or body weight in this 2-year study, suggesting that higher doses would probably have been tolerated. In a tumour-promotion study in F344 female rats, Dean *et al.* (2002) gave PCB-153 at a dose of 10 000 µg/kg bw by gavage, three times per week, for 8 weeks, and observed only a significant increase in liver weight.]

(c) PCB-118

Rat

Groups of 80 female Harlan Sprague-Dawley rats (age, 8 weeks) were given PCB-118 (purity, > 99%) at a dose of 0 (vehicle control), 100, 220, 460, 1000, or 4600 µg/kg bw in corn oil : acetone (99 : 1) by gavage, 5 days per week, for up to 105 weeks (core study) (Yoshizawa *et al.*, 2009; NTP, 2010). Ten rats per group were evaluated at 14, 31, or 53 weeks. A stop-exposure group of 50 female rats was given PCB-118 at a dose of 4600 µg/kg bw in corn oil : acetone (99 : 1) by gavage for 30 weeks, then the vehicle for the remainder of the study. At the 53-week interim evaluation, three cholangiocarcinomas and one hepatocellular adenoma were observed in the group at 4600 µg/kg bw. At 2 years, the incidences of multiple cholangiocarcinoma, and single or multiple cholangiocarcinoma (combined) in the group at 4600 µg/kg bw and the stop-exposure group were significantly greater than those in the vehicle-control group. The incidences of multiple hepatocellular adenoma in the group at 4600 µg/kg bw, and single or multiple hepatocellular adenoma (combined) in the groups at 1000 µg/kg bw or 4600 µg/kg bw were significantly greater than those in the vehicle-control group. Four rats developed hepatocholangioma and one rat developed hepatocellular carcinoma in the group at 4600 µg/kg bw. Significantly increased incidences of multiple cystic keratinizing epithelioma of the lung and of single or multiple cystic keratinizing epithelioma (combined) occurred in the group at 4600 µg/kg bw compared with the vehicle-control group. The incidence of uterine carcinoma in the stop-exposure group was significantly greater than that in the vehicle-control group; a slight increase in the incidence of squamous cell carcinoma of the uterus occurred in the group at 220 µg/kg bw, and single incidences occurred at 460 µg/kg bw, 1000 µg/kg bw, and in the stop-exposure group. There were slightly increased incidences of exocrine pancreatic adenoma in core-study groups receiving PCB-118 at doses of 460 µg/kg bw or higher.

Table 3.3 Description of binary mixtures of PCB-126 and PCB-153 given to rats in a study of carcinogenicity by the NTP (2006c)

Group	Total TEQ (ng TEQ/kg bw)	Mass	
		PCB-126 (ng/kg bw)	PCB-153 (μg/kg bw)
Constant ratio mixture			
1	Vehicle control	0	0
2	1	10	10
3	10	100	100
5	30	300	300
7	100	1000	1000
Varying ratio mixture			
1	Vehicle control	0	0
4	30	300	100
5	30	300	300
6	30	300	1000

PCB, polychlorinated biphenyl; TEQ, toxic equivalent

(d) PCB-126 and PCB-153

Rat

The NTP conducted a 2-year study that was designed to assess the carcinogenicity of a mixture of PCB-126 and PCB-153 in a constant ratio, and a mixture of PCB-126 and PCB-153 in varying ratios to assess the effect of increasing PCB-153 (NTP, 2006c; Yoshizawa *et al.*, 2009). Groups of 81 or 80 female Harlan Sprague-Dawley rats (age, 8 weeks) received a mixture of PCB-126 and PCB-153 in corn oil : acetone (99 : 1) by gavage, 5 days per week, for up to 105 weeks. Dose groups were referred to by the total concentrations of toxic equivalents (TEQ) provided by the PCBs in the mixture per kg bw in each group (see Table 3.3); a control group of 81 female rats received the corn oil : acetone vehicle only (group 1). Ten rats per group were evaluated at 14, 31, and 53 weeks. At 2 years, the incidences of hepatocellular adenoma (single or multiple) in group 7 (constant ratio; TEQ, 100 ng/kg bw), and of cholangiocarcinoma (single or multiple) in group 5 (constant ratio; TEQ, 30 ng/kg bw) or group 7 were significantly increased. The incidence of hepatocholangioma was also significantly increased in group 7. Two rats in group 7 had hepatocellular carcinoma; no hepatocellular carcinoma was reported in the historical vehicle controls. In the varying-ratio study, increasing the proportion of PCB-153 significantly increased the incidences of hepatocellular adenoma and cholangiocarcinoma. In the constant-ratio study, the incidence of cystic keratinizing epithelioma of the lung was significantly increased in group 7. In addition, one squamous cell carcinoma was reported in group 5 and one in group 7. Significantly increased incidences of gingival squamous cell carcinoma of the oral mucosa occurred in groups 5 and 7. There was also a slight increase in the incidence of uterine squamous cell carcinoma in group 5.

(e) PCB-118 and PCB-126

Rat

Groups of 81 female Harlan Sprague-Dawley rats (age, 9 weeks) were given a binary mixture of PCB-118 and PCB-126 (see Table 3.4) at a dose of 0 (vehicle control), 7, 22, 72, 216 ng TEQ/kg bw, by gavage in corn oil : acetone (99 : 1), 5 days per week, for up to 104 weeks; a group of 86 female rats received the mixture at a dose of 360 ng TEQ/kg bw (Yoshizawa *et al.*, 2005, 2007,

Table 3.4 Composition of a mixture of PCB-118 and PCB-126 given to rats in a study of carcinogenicity by the NTP (2006d)

	PCB-118	PCB-126	PCB-77[a]	PCB-167[a]
Percentage of bulk mass[b]	98.5	0.6	0.2	0.5
Percentage of total TEQ[c]	13.7	86.3	0.03	0.007

[a] Present as contaminants that were not considered to contribute to the dioxin-like activity of the bulk synthesized test article
[b] Based on the level of each compound present in the bulk synthesized test article
[c] Assuming WHO toxic equivalency factor (TEF) values of 0.1 (PCB-126), 0.0001 (PCB-118), 0.0001 (PCB-77) and 0.00001 (PCB-167)
PCB, polychlorinated biphenyl; TEQ, toxic equivalent

2009; NTP, 2006d). Ten rats per group were evaluated at 14, 31, or 53 weeks. In the stop-exposure group, 50 female rats received the mixture at a dose of 360 ng TEQ/kg bw for 30 weeks, and then the vehicle only for the remainder of the study. The dose groups are described in Table 3.5. The mixture contained predominantly PCB-118 (by mass) and PCB-126 (by TEQ), but also contained PCB-77 and PCB-167 as contaminants that were not considered to contribute to the dioxin-like activity of the bulk synthesized material (see Table 3.4).

No rats at 216 or 360 ng TEQ/kg bw survived to the end of the study; survival in the stop-exposure group was also significantly lower than in the vehicle-control group, with only 10 rats surviving to the end of the study. Mean body weights of rats receiving 72 ng TEQ/kg bw or more were lower than those of rats in the vehicle-control group throughout most of the study. At 2 years, the incidences of cholangiocarcinoma (single or multiple, combined) and cholangiocarcinoma (multiple) were significantly increased in groups receiving 72 ng TEQ/kg bw or more. The incidence of hepatocellular adenoma was also significantly increased in the groups at 216 and 360 ng TEQ/kg bw. In addition, single occurrences of hepatocholangioma, cholangioma, or hepatocellular carcinoma were observed in some groups receiving 72 ng TEQ/kg bw or more. At 53 weeks, the incidence of cystic keratinizing epithelioma of the lung was significantly increased in the group at 216 ng TEQ/kg bw. At 2 years, significantly increased incidences of cystic keratinizing epithelioma (single or multiple, combined) and of cystic keratinizing epithelioma (multiple) were reported in groups receiving 72 ng TEQ/kg bw or more. Non-statistically significant increased incidences of gingival squamous cell carcinoma of the oral mucosa were observed at the end of the 2-year study.

3.1.2 Commercial mixtures of PCBs

(a) Aroclor 1254

(i) Mouse

In a study on the activity of Aroclor 1254 in mice with different aryl hydrocarbon receptor (AhR) phenotypes, groups of 23–34 male C57BL/6, DBA/2, or B6D2F1 mice (age, 5 weeks) were initiated with a single intraperitoneal dose of *N*-nitrosodiethylamine (NDEA) at 0 or 90 mg/kg bw, in tricaprylin. Three weeks later, the mice were placed on a diet containing Aroclor 1254 at a concentration of 100 ppm or the control diet for 20 weeks. After the promotion phase, the mice were left untreated until the terminal kill at age 52 weeks. Aroclor 1254 alone did not increase the incidence of tumours of the lung or liver in any of the three strains compared with their respective controls (Beebe *et al.*, 1995).

Four groups of 50 male BALB/cJ inbred mice (age, 5–6 weeks) were fed diets containing Aroclor 1254 (mixed with corn starch) at a concentration of 0 (control) or 300 ppm for up to 11 months (Kimbrough & Linder, 1974; Faroon *et al.*, 2001). After 6 months of exposure, one group of treated mice was fed the standard diet,

Table 3.5 Doses of PCB-118 and PCB-126 given to rats in a study of carcinogenicity by the NTP (2006d)

Dose (ng TEQ/kg bw)	Contribution to dose by mass[b]				Contribution to dose by TEQ[c] (ng TEQ/kg bw)				Total nominal dose by TEQ[c] (ng TEQ/kg bw)

[a] Present as contaminants that were not considered to contribute to the dioxin-like activity of the bulk synthesized test article
[b] Based on the level of each compound present in the bulk synthesized test article
[c] Assuming WHO TEF (toxic equivalency factor) values of 0.1 (PCB-126), 0.0001 (PCB-118), 0.0001 (PCB-77) and 0.00001 (PCB-167). TEQ value for PCB-118 was calculated assuming 98.5% of bulk material is PCB-118
[d] Nominal dose (µg/kg bw) of bulk synthesized material
PCB, polychlorinated biphenyl; TEQ, toxic equivalent

while the other treated group was fed the experimental diet for an additional 5 months; the two control groups were fed plain chow for an additional 5 months. Only one of 24 surviving mice given Aroclor 1254 for 6 months had a hepatoma [histopathology not further specified], while the incidence of hepatoma in the 22 surviving mice fed Aroclor 1254 for 11 months was significantly increased (10 out of 22; $P < 0.001$). Hepatomas were not found in any of the mice in the control groups.

(ii) Rat

Groups of 24 male and 24 female F344 rats (age, 7 weeks) were fed diets containing Aroclor 1254 at a concentration of 0, 25, 50, or 100 ppm in corn oil for up to 105 weeks (NTP, 1978; Ward, 1985; Safe, 1989; Silberhorn *et al.*, 1990; Faroon *et al.*, 2001). In males, hepatocellular adenoma was observed in one, two, and five of the rats at the lowest, intermediate, and highest dose, respectively, and hepatocellular carcinoma was observed in two rats at the highest dose; the incidences of hepatocellular adenoma and of hepatocellular adenoma or carcinoma (combined) in males at the highest dose were statistically significantly increased. Hepatocellular tumours were not observed in controls. Non-statistically significant low incidences of rare adenocarcinomas of the glandular stomach were observed in both sexes. Adenocarcinoma of the glandular stomach was not observed in controls. The historical incidence of adenocarcinoma of the glandular stomach at the study laboratory (6 out of 600 males [1%], 2 out of 600 females [0.3%]) suggested that the occurrence of these tumours, although not statistically significant, may have been related to the administration of Aroclor 1254. There was a statistically significant dose-related trend in the combined incidences of lymphoma and leukaemia in male rats, but incidence in each dose group was not statistically significantly different from that in matched controls. Morgan *et al.* (1981) and Ward (1985) re-examined the gastrointestinal lesions observed in the study by the NTP (1978) and found a dose-related increase in the incidence of metaplasia of the glandular stomach, and also found adenocarcinoma of the glandular stomach in six treated rats. When compared with the incidence of adenocarcinoma of the glandular stomach in historical controls (1 out of 3548), the total incidence (6 out of 144 male and female rats treated with Aroclor 1254) was statistically significant.

(b) Aroclor 1260

Rat

Groups of 200 female Sherman rats (age, 21–26 days) were fed diets containing Aroclor 1260 at a concentration of 0 (control) or 100 ppm for approximately 21 months (Kimbrough *et al.*, 1975). The rats were killed at age 23 months. There were statistically significant increases in the incidences of "hepatic neoplastic nodules" and of hepatocellular carcinoma in rats receiving Aroclor 1260 compared with controls. The hepatocellular tumours were re-evaluated histologically by a panel of pathologists using contemporary diagnostic criteria and nomenclature (Moore *et al.*, 1994). Lesions that had been previously diagnosed as "neoplastic nodules" were reclassified as either hepatocellular hyperplasia or hepatocellular adenoma. In general, the results of the re-evaluation were consistent with those of the original evaluation.

Groups of 32 male Wistar rats (age, 5 weeks) were fed a 10% protein diet containing Aroclor 1260 (dissolved in coconut oil) at a concentration of 0 (control), 50, or 100 ppm for 120 days (Rao & Banerji, 1988; Silberhorn *et al.*, 1990). Controls were fed diet mixed with coconut oil. The incidences of "liver neoplastic nodules" [liver tumours] were significantly increased in both groups of treated rats; however, the incidence of tumours in rats fed the higher dose was lower than that in rats fed the lower dose.

Groups of 70 male and 70 female Sprague-Dawley rats were fed a diet containing Aroclor 1260 at a concentration of 100 ppm for 16 months, followed by diet containing Aroclor 1260 at 50 ppm for an additional 8 months, and then basal diet for 5 months (Norback & Weltman, 1985; Safe, 1989; Silberhorn *et al.*, 1990; Moore *et al.*, 1994; Faroon *et al.*, 2001). Groups of 63 males and 63 females served as controls and received the basal diet supplemented with corn oil for 18 months, and then the basal diet only for the remainder of the study. The medial and left lobes of the liver of 10 rats (two male controls, two female controls, three PCB-treated males and three PCB-treated females, for each time-point) were removed at 1, 3, 6, 9, 12, 15, and 18 months. In treated rats that survived 18 months or longer, malignant hepatic tumours (adenocarcinoma and/or trabecular carcinoma) were found in 43 out of 47 females, but only in 2 out of 46 males. The individual incidences of adenocarcinoma and of trabecular carcinoma in PCB-treated females were significantly greater than in controls. Hepatic neoplastic nodules [benign hepatocellular tumours] occurred in 5 out of 46 males, and 2 out of 47 females. A single hepatic neoplastic nodule occurred in a female control rat. PCB-exposed rats developed cystic cholangioma in 2 out of 46 males, and 5 out of 47 females [non-significant], versus 0 out of 32 males and 1 out of 49 females among the controls. Preneoplastic lesions of the biliary tract, referred to as simple and cystic cholangioma, also occurred at a higher incidence in treated males and females (30% and 45%, respectively).

(c) Aroclor 1016, 1242, 1254, and 1260

Rat

A comprehensive comparative long-term study of toxicity and carcinogenicity was conducted with four of the most widely used commercial Aroclor mixtures: Aroclor 1016, 1242, 1254, and 1260 (Mayes *et al.*, 1998; Faroon *et al.*, 2001; Brown *et al.*, 2007). Groups of 50 male and 50 female Sprague–Dawley rats (age, 6–8 weeks) were fed diets containing Aroclor 1016, 1242, 1254, or 1260 at doses ranging from 25 to 200 ppm (three dose levels for Aroclor 1016, 1254 and 1260, and two dose levels for Aroclor 1242) for 24 months. Groups of 100 males and 100 females served as controls. Aroclor 1016, 1242, 1254, and 1260 contained polychlorinated dibenzodioxins (PCDDs) at concentrations of 0.6, 0, 20, and 0 ppb, respectively, and polychlorinated dibenzofurans (PCDFs) at concentrations

of 0.035, 2.9, 23, and 4.9 ppm, respectively. The basal diet contained PCBs at less than 0.15 ppm (estimated dose, < 0.01 mg/kg bw per day). Aroclor 1254 was treated to remove > 99% of the PCDFs. Feeding with diets containing Aroclor led to increased incidences of hepatic neoplasms (primarily hepatocellular adenoma) that were highly sex-dependent (females > males) and that differed between Aroclor mixtures. For females, the incidences of hepatocellular adenoma and of hepatocellular carcinoma increased with dose, with the following pattern: Aroclor 1254 > Aroclor 1260 > Aroclor 1242 > Aroclor 1016. The number of females bearing multiple hepatocellular tumours also increased in a dose-related manner for all Aroclor mixtures, and the highest numbers were in the groups receiving the intermediate and highest dose of Aroclor 1254, and the highest dose of Aroclor 1260. In addition, in females receiving Aroclor 1260, there was an increase in the incidence of cholangioma. In males, an increased incidence of hepatocellular adenoma was observed only in the group receiving Aroclor 1260 at the highest dose. The incidence of follicular cell adenoma of the thyroid gland was significantly increased in males in a non-dose-dependent manner; these increases were induced by Aroclor 1242 (both doses), Aroclor 1254 (all doses), and Aroclor 1260 (lowest and intermediate doses).

(d) Kanechlor 300, 400, and 500

(i) Mouse

Groups of 20 male and 20 female dd strain albino mice [age not reported] were given diets containing one of three PCB mixtures (Kanechlor 300, 400, or 500) at a concentration of 0, 100, 250, or 500 ppm for 24 or 32 weeks (Nagasaki *et al.*, 1975). The incidence of hepatocellular carcinoma was significantly increased in male and female mice given Kanechlor 500 at 500 ppm for 32 weeks. No tumours of the liver were found in mice fed Kanechlor 500 at dietary concentrations of 100 or 250 ppm, or the lesser chlorinated commercial mixtures Kanechlor 400 or Kanechlor 300 at any of the three dietary concentrations at 24 or 32 weeks.

Groups of 12 male dd strain albino mice (age, 8 weeks) were fed basal diets supplemented with one of three PCB mixtures (Kanechlor 300, 400, or 500) at a concentration of 100, 250, or 500 ppm for 32 weeks; a control group of six mice was fed basal diet alone (Ito *et al.*, 1973; Silberhorn *et al.*, 1990; Faroon *et al.*, 2001). The incidences of hepatocellular carcinoma (5 out of 12 [not significant]) and liver hyperplastic nodules [some of which may have been hepatocellular adenomas] (7 out of 12 [$P < 0.05$]) were increased in mice fed diets containing Kanechlor 500 at 500 ppm compared with controls (0 out of 6). Hepatic lesions were not found in mice fed Kanechlor 500 at lower doses, or in mice exposed to the less chlorinated mixtures Kanechlor 400 or Kanechlor 300 for 32 weeks. Other histopathological changes in mice treated with PCBs included oval-cell proliferation, bile duct proliferation, hepatocyte hypertrophy, and amyloidosis. [The Working Group noted that the study may have been limited by the small number of mice, the relatively short treatment period, and the absence of an observation period after treatment.]

(ii) Rat

A group of 10 male and 10 female Donryu rats (age, 10 weeks) were fed diet containing Kaneclor 400 at a concentration of 38.5 ppm for 4 weeks, then the initial concentration was increased (based on body weights) twice for 8 weeks, 4 times for 3 weeks, 8 times for 3 weeks, and 16 times for 8 weeks (Kimura & Baba, 1973; Silberhorn *et al.*, 1990). The latter concentration was decreased to 12 times for 32 weeks because body weights were decreasing markedly. Rats were then fed basal diet until moribund, up to 560 days. A group of five males and five females fed basal diets served as controls. Treatment with Kanechlor 400 (duration, 400 days) caused

a significant increase in the incidence of multiple adenomatous nodules [hepatocellular adenoma] in females. None of the treated males developed adenomatous nodules. [The Working Group noted that the study may have been limited by the small numbers of animals, and may have exceeded the maximum tolerated dose.]

(e) Clophen A 30 and Clophen A 60

Rat

Male weanling Wistar rats were fed a diet supplemented with Clophen A 30 (42% chlorine by weight) or Clophen A 60 (60% chlorine by weight) at a concentration of 100 ppm, or an estimated dose of 5 mg/kg bw per day, for up to 832 days; controls were fed the basal diet (Schaeffer *et al.*, 1984; Young, 1985; Safe, 1989). Tumour incidence was investigated at intervals of 100 days. After 800 days, the overall incidence of hepatocellular neoplastic nodules, irrespective of time period, was significantly increased in rats fed Clophen A 30 (38 out of 130) or Clophen A 60 (63 out of 126) compared with controls (5 out of 131). The incidence of hepatocellular carcinoma was significantly increased in rats fed Clophen A 60 (61 out of 126 compared with 1 out of 131 controls). The incidences of hepatocellular lesions were re-evaluated by a panel of pathologists using contemporary diagnostic criteria and nomenclature (Moore *et al.*, 1994). Lesions that had been previously diagnosed as neoplastic nodules were now classified as either hepatocellular hyperplasia or hepatocellular adenoma. The results of the re-evaluation were generally consistent with those of the original evaluation.

3.2 Transplacental and perinatal exposure

This section covers those studies for which exposure to PCBs occurred either transplacentally and/or perinatally. This period generally covers exposure from day 1 of gestation until weaning on postnatal day 21, although it should be noted that weaning can occur at up to age 28 days.

3.2.1 Individual PCBs and binary mixtures

(a) PCB-126

See Table 3.6

Rat

Five groups of pregnant Sprague-Dawley rats were given PCB-126 at a dose of 0 (corn oil), 0.025, 2.5, 250, or 7500 ng/kg bw by gavage on days 13 to 19 of gestation. Female pups from the exposed dams were weaned on postnatal day 21, and subsequently exposed at age 50 days to 7,12-dimethylbenz[*a*]anthracene (DMBA) at a dose of 20 mg/kg bw in corn oil by gavage, and followed until age 170 days (Muto *et al.*, 2001). There was no specific perinatal oral exposure to PCB-126. There was a significant reduction in body weight in the groups of pups at 250 ng/kg bw and 7500 ng/kg bw at postnatal day 21, and at 7500 ng/kg bw at age 30 days. There was a significant reduction in the incidence of DMBA-induced tumours of the mammary gland in the group at 7500 ng/kg bw. In the group at 7500 ng/kg bw, 41% of tumours were adenomas, while tumours in all other groups were mainly adenocarcinomas. [The study design was not a full carcinogenesis bioassay of PCBs.]

In a similar study by Wakui *et al.* (2005), four groups of pregnant Sprague-Dawley rats were given PCB-126 at a dose of 0 (corn oil vehicle), 2.5, 250, or 7500 ng/kg bw by gavage on days 13 to 19 of gestation. Female pups from the exposed dams were weaned at postnatal day 21, and subsequently exposed at age 50 days to DMBA at a dose of 100 mg/kg bw in corn oil by gavage, and followed until age 150 days. As in the study by Muto *et al.* (2001), there was a significant reduction in the incidence of adenocarcinoma of the mammary gland in the group at 7500 ng/kg bw. [The study design was not a full carcinogenesis bioassay of PCBs.]

Table 3.6 Studies of carcinogenicity in rats exposed perinatally or transplacentally to PCB-126

Strain (sex) Duration Reference	Dosing regimen, Animals/group at start	For each target organ: incidence (%), multiplicity of tumours	Significance	Comments
Sprague-Dawley (Japan SLC) (F) 170 day Muto *et al.* (2001)	Dams were treated with PCB-126 at 0 (corn oil vehicle), 0.025, 2.5, 250, or 7500 ng/kg bw (0.5 mL/rat) by gavage on days 13–19 of gestation. Pups were weaned at PND 21 Female pups (age 50 days) received DMBA at 20 mg/kg bw in corn oil by gavage and observed until age 170 days, or until tumours reached 20 mm in size Group 1: corn oil vehicle Group 2: 0.025 ng/kg bw Group 3: 2.5 ng/kg bw Group 4: 250 ng/kg bw Group 5: 7500 ng/kg bw 45/group	Tumours of the mammary gland: Group 1: 42/45, 3.12 ± 0.74 Group 2: 44/45, 2.77 ± 1.89 Group 3: 42/45, 3.98 ± 2.82 Group 4: 43/45, 5.09 ± 2.42 Group 5: 35/45*, 2.25 ± 1.55	*$P < 0.05$, χ^2 test (decrease)	Not a full carcinogenesis bioassay In the group at 7500 ng/kg bw, 41% of tumours were adenomas, whereas in all other groups the tumours were mainly adenocarcinomas
Sprague-Dawley (Japan SLC) (F) 150 day Wakui *et al.* (2005)	Dams were treated with PCB-126 at 0 (corn oil vehicle), 2.5, 250, 7500 ng/kg bw (0.5 mL/rat) by gavage on days 13–19 of gestation. Pups were weaned at PND 21 Females (age 50 days) received DMBA at 100 mg/kg bw in corn oil by gavage, and were observed until age 150 days Group 1: corn oil vehicle Group 2: 2.5 ng/kg bw Group 3: 250 ng/kg bw Group 4: 7500 ng/kg bw 25/group	Mammary gland, adenocarcinoma: Group 1: 22/25 (88%) Group 2: 21/25 (84%) Group 3: 23/25 (92%) Group 4: 16/25 (64%)*	*$P < 0.05$, χ^2 test (decrease)	Not a full carcinogenicity bioassay

DMBA, 7,12-dimethylbenz[*a*]anthracene; F, female; M, male; NDMA, *N*-nitrosodimethylamine; PND, postnatal day; wk, week

(b) PCB-153 and PCB-138

See Table 3.7

Mouse

Eight groups of male Swiss Cr:NIH(s) mice were given an intraperitoneal injection of *N*-nitrosodimethylamine (NDMA) at 0 (saline vehicle) or 5 mg/kg bw on postnatal day 4. On postnatal day 8, the mice were treated by gavage with PCB-153 or PCB-138, or a mixture of the two PCBs, each at a single dose of 20 mg/kg bw, or with the vehicle, olive oil (Anderson *et al.*, 1991). The concentration selected, 20 mg/kg bw, is approximately equivalent to the concentration of each PCB congener in a dose of 500 mg/kg bw of Aroclor 1254. The mice were killed at age 16 weeks. There was no effect of either PCB congener alone or in combination on the incidence of bronchioloalveolar adenoma in the absence of treatment with NDMA. In NDMA-initiated mice, there was a significant increase in the multiplicity of bronchioloalveolar adenoma in mice also exposed to PCB-138. There was no effect of PCB-153, or of PCB-153 plus PCB-138, when compared with controls treated with NDMA only. [This study was not a full carcinogenesis bioassay. It was limited regarding the effect of the PCBs alone without initiation, due to the short duration of observation.]

3.2.2 Commercial mixtures of PCBs

(a) Aroclor 1254

See Table 3.8

Mouse

Pregnant CD-1 mice were given a single intraperitoneal injection of Aroclor 1254 at a dose of 0 (corn oil) or 500 mg/kg bw on day 19 of gestation (Anderson *et al.*, 1983). Suckling mice were given NDMA at 0 (saline vehicle) or 5 mg/kg bw by intraperitoneal injection on postnatal day 4 or 14, or every 3 days on postnatal days 1–22. Mice were weaned at age 4 weeks and examined at approximately 28 weeks and 18 months. No tumours of the liver were found at 28 weeks in male or female mice exposed in utero to the vehicle or Aroclor 1254 alone without exposure to NDMA. At 18 months, there was no increase in the incidence of tumours of the liver in mice treated with Aroclor 1254 without NDMA exposure. In the groups that were exposed to NDMA on postnatal day 4 or 14, there was no effect of maternal exposure to Aroclor 1254 on the incidence or multiplicity of tumours of the liver in male or female mice. Nevertheless, at 18 months, there was a significant increase in the incidence of "coalescing" tumours of the liver in females exposed on postnatal day 4 and in males exposed on postnatal day 14. There was no effect of maternal exposure to Aroclor 1254 on the incidence or multiplicity of tumours of the liver in male or female pups treated with NDMA between postnatal days 1 and 22. [This study design was not a full carcinogenesis bioassay of PCBs. Although mice were exposed to PCBs before being exposed to NDMA, NDMA acts as an initiator. Thus results from the groups exposed to NDMA plus PCBs are more likely to reflect an effect of the exposure to PCBs in utero on NDMA carcinogenesis.]

Groups of male neonatal Swiss Cr:NIH(s) mice were injected intraperitoneally with NDMA at a dose of 5 mg/kg bw in saline on postnatal day 4 (Anderson *et al.*, 1986). On postnatal day 8, mice were exposed to Aroclor 1254 at a dose of 0 (control), 50, 250, or 500 mg/kg bw in olive oil by gavage, for 16 or 28 weeks. The study also included two non-initiated groups exposed to Aroclor 1254 at a dose of 0 or 500 mg/kg bw. A significant increase in the average number of bronchioloalveolar adenomas was observed in mice exposed to both NDMA and Aroclor 1254 compared with mice exposed to NDMA only, but not in mice exposed to Aroclor 1254 without NDMA initiation compared with mice exposed to vehicle only.

Table 3.8 (continued)

Strain (sex) Duration Reference	Dosing regimen, Animals/group at start	For each target organ: incidence (%), multiplicity of tumours	Significance	Comments
Swiss Cr:NIH(s) (M) up to 72 wk Anderson *et al.* (1994)	Intraperitoneal injection on PND 4 with NDMA at 5 mg/kg bw or saline vehicle. At age 8 days, mice received Aroclor 1254 at 250 mg/kg bw by gavage in olive oil or vehicle only. Mice were killed when moribund or at age 16, 28, 52, or 72 wk Groups were exposed to: NDMA; NDMA + Aroclor 1254; Aroclor 1254; saline/oil Number/group, NR	*Bronchioloalveolar adenoma:* Age 28 wk: 7/23[a] (30%), 0.5 ± 1.1[b]; 19/27[a] (70%), 1.9 ± 2.9[b]; 0/13; 0/16 Age 52 wk: 12/25 (48%), 0.6 ± 0.8[c]; 15/23 (65%), 2.7 ± 3.8[c]; 4/24 (17%), 0.17 ± 0.38; 6/27 (22%), 0.26 ± 0.4 Age 72 wk: 21/23 (91%), 5.1 ± 4.5; 17/23 (74%), 3.9 ± 4.3; 17/25 (68%), 0.9 ± 0.8; 17/39 (44%), 0.6 ± 0.7 *Liver adenoma:* Age 52 wk: 1/25[d] (4%), 0.04 ± 0.2; 9/23[d] (39%), 0.6 ± 0.8; 0/24; 0/27 Age 72 wk: 16/23 (70%), 1.8 ± 2.2; 14/25 (56%), 1.5 ± 2.0; 0/25; 0/39	Matched letters are significantly different from each other [a]$P = 0.01$ [b]$P = 0.0033$ [c]$P = 0.0496$ [d]$P = 0.004$	Purity, NR Not a full carcinogenicity bioassay

mo, month; NDMA, *N*-nitrosodimethylamine; NR, not reported; NS, not significant; PND, postnatal day; wk, week

In a subsequent experiment, groups of neonatal male Swiss Cr:NIH(s) mice were given an intraperitoneal injection of NDMA at a dose of 0 (saline vehicle) or 5 mg/kg bw on postnatal day 4, then given Aroclor 1254 at a dose of 0 or 250 mg/kg bw in olive oil on day 8 by gavage, and killed at age 16, 28, 52, or 72 weeks (Anderson *et al.*, 1994). At age 28 weeks, the incidence of bronchioloalveolar adenoma in mice initiated with NDMA was increased 2.5-fold by treatment with Aroclor 1254. The multiplicity of bronchioloalveolar adenoma was enhanced fourfold by treatment with Aroclor 1254 for 28 or 52 weeks. By 72 weeks, tumour numbers, although high, were similar in the groups receiving NDMA only, and NDMA plus Aroclor 1254. There was an increased incidence of liver adenoma at 52 weeks in mice receiving NDMA plus Aroclor 1254 compared with mice receiving NDMA only. By 72 weeks, the incidences in the groups receiving NDMA or NDMA plus Arochlor 1254 were similar. [This study was not a full carcinogenesis bioassay of PCBs.]

(b) Kanechlor 500

See Table 3.9

Rat

Pregnant Wistar rats were exposed to Kanechlor 500 at a dose of 0 (olive oil vehicle), 40, or 200 mg/kg bw by gavage on days 5, 10, and 15 of gestation (Nishizumi, 1980). Male and female pups were subsequently weaned and given drinking-water containing NDEA at 50 ppm for 5 weeks to induce liver tumours [mainly hepatocellular carcinomas] that were evaluated after 20 and 24 weeks. The average concentration of total PCBs in the liver at 4 weeks was 1 ppm, 18 ppm and 360 ppm in the groups at 0 (vehicle), 40 mg/kg bw and 200 mg/kg bw, respectively, indicating clear transfer from the dam to the offspring. In both males and females, there was a decrease in the multiplicity of NDEA-initiated tumours of the liver. [This study was not a full carcinogenesis bioassay.]

3.2.3 Mixtures of PCBs and other chlorinated agents found in human milk fat

*(a) Mixture of non-*ortho *PCBs, PCDFs, and PCDDs*

See Table 3.10

Rat

Female Sprague-Dawley rats were exposed by gavage at age 1, 5, 10, 15, and 20 days to a mixture of three non-*ortho* PCBs [PCB-77, PCB-126, and PCB-169], six PCDDs, and seven PCDFs, or were exposed to the vehicle (corn oil) only (Desaulniers *et al.*, 2004). The concentrations of these agents in the mixture were based on the concentrations of dioxin-like congeners found in human milk fat, and the doses administered were equal to 10 times, 100 times, or 1000 times the quantities found in milk fat. At age 50 days, groups of rats were injected intraperitoneally with *N*-methyl-*N*-nitrosourea (MNU) at a dose of 0 or 30 mg/kg bw to induce the development of tumours of the mammary gland. At age 32 weeks, in those groups not treated with MNU, there was a significant increase in the incidence of benign lesions of the mammary gland (adenoma, fibroadenoma, and hyperplasia) after exposure to the 1000-times mixture. In the MNU-treated groups, there was no effect of exposure to the mixture on the incidences of benign lesions or malignant tumours of the mammary gland. [This study was not a full carcinogenesis bioassay. Given the presence of PCDDs and PCDFs in the mixture, conclusions regarding the effect of PCBs alone could not be drawn from this study.]

(b) Mixture of PCBs, DDT, and DDE

See Table 3.11

Rat

Neonatal female Sprague Dawley rats were exposed to a mixture of 19 PCB-congeners, *p,p´*-dichlorodiphenyltrichloroethane (DDT), and *p,p´*-dichlorodiphenyldichloroethene (DDE)

Table 3.9 Study of carcinogenicity in rats exposed transplacentally and perinatally to Kanechlor 500

Sprague-Dawley (F) 308 days or when tumour size reached 1 cm Desaulniers *et al.* (2001)	Neonates treated by gavage at age 1, 5, 10, 15, and 20 days with a mixture[a] containing 0 (vehicle), 10, 100 or 1000 times the amount of PCBs, DDT, DDE that a human baby would consume. A separate group received TCDD at 2.5 µg/kg bw by gavage on day 18. On day 21, groups 3–7 received a single intraperitoneal injection of MNU at 30 mg/kg bw in saline Group 1: corn oil vehicle controls Group 2: 1000 × mixture Group 3: MNU + corn oil vehicle Group 4: MNU + 10 × mixture Group 5: MNU + 100 × mixture Group 6: MNU + 1000 × mixture Group 7: MNU + TCDD 33–41/group	*Mammary gland* Groups 1 and 2: Fibroadenoma: 1/30, 0/33 Adenoma: 0/30, 0/33 Papilloma: 0/30, 0/33 Carcinoma in situ: 0/30, 1/33 Adenocarcinoma: 0/30, 0/33 Benign or malignant lesions (combined): 1/30, 2/33 Groups 3–7: Fibroadenoma: 12/41, 13/28, 6/31, 9/34, 10/32 Adenoma: 5/41, 4/28, 4/31, 8/34, 6/32 Papilloma: 3/41, 1/28, 3/31, 1/34, 5/32 Carcinoma in situ: 5/41, 5/28, 8/31, 7/34, 4/32 Adenocarcinoma: 11/41, 12/28, 10/31, 12/34, 13/32 Benign or malignant lesions (combined): 28/41, 24/28, 22/31, 25/34, 25/34 Benign or malignant lesions (median number of lesions): 2, 2, 1, 4.5*, 5.5	Group 2 vs group 1: NS Groups 4–7 vs group 3: NS for incidence *P = 0.05	Purity, NR Mixture included DDT and DDE, so conclusions could not be made regarding the effect of PCBs alone Not a full carcinogenesis bioassay

[a] Mixture consists of *p,p´*-dichlorodiphenyltrichloroethane (DDT), *p,p´*-dichlorodiphenyldichloroethene (DDE) and PCBs mixture comprised of non-*ortho* (PCB-77, -126, -169), mono-*ortho* (PCB-28, -66, -74, -118, -156) and di-*ortho* (PCB-99, -128, -138, -153, -170, -180, -183, -187, -194, -201, -203) substituted congeners detected in > 75% of breast milk samples from Canadian women. DDT, DDE and PCBs were included in the mixture according to the median concentrations in milk fat

MNU, *N*-methyl-*N*-nitrosourea; NS, not significant; PCB, polychlorinated biphenyl; TCDD, 2,3,7,8-tetrachlorodibenzo-*para*-dioxin; vs, versus

(Desaulniers *et al.*, 2001). The PCB-congeners in the mixture were those detected in more than 75% of samples of breast milk from Canadian women and were included in proportions determined by their median concentrations measured in milk fat. The PCBs were: non-*ortho* (PCB-77, PCB-126, PCB-169), mono-*ortho* (PCB-28, PCB-66, PCB-74, PCB-118, PCB-156), and di-*ortho* (PCB-99, PCB-128, PCB-138, PCB-153, PCB-170, PCB-180, PCB-183, PCB-187, PCB-194, PCB-201, PCB-203) substituted congeners. In this study, five groups of neonatal rats were exposed to the mixture composed of DDT, its major metabolite DDE, and PCBs at 0 (corn oil), 10, 100, or 1000 times their concentrations in breast milk, by gavage, starting at age 1, 5, 10, 15, or 20 days. For comparison purposes, an additional group was exposed by gavage at age 18 days to 2,3,7,8-tetrachlorodibenzo-*para*-dioxin (TCDD) at a concentration of 2.5 µg/kg bw. On day 21, all treatment groups (except for a control group that received corn oil only, and a group that received the 1000-times mixture) received a single intraperitoneal injection of MNU (30 mg/kg bw) in saline. Animals were observed up to 308 days. Seven to nine rats from the groups not exposed to MNU were killed between ages 55 and 62 days; the remaining rats were killed at 224 days. MNU-treated rats were killed when palpable tumours reached 1 cm, or by day 308 if no palpable tumour was detected. Sporadic incidences of lesions of the mammary gland were observed in the groups not treated with MNU (0 and 1000-times mixture). On the contrary, a large number of lesions of the mammary gland (including hyperplasia, the most common lesion observed) were seen in MNU-treated rats, and there was a significant effect of the 1000-times mixture ($P = 0.05$) on the median number of combined benign and malignant lesions of the mammary gland when compared to the MNU-only treated rats. There was no significant effect on the incidence of any specific tumour type, either benign or malignant, or the combined incidence of benign and malignant neoplasms. [Given that the mixture contained DDT and DDE, in addition to PCBs, the Working Group considered this study as a co-carcinogenicity study, and conclusions regarding the effect of PCBs alone could not be made.]

3.2.7 PCB metabolites: 4′-OH-PCB-30 and 4′-OH-PCB-61

See Table 3.12

Mouse

Neonatal female BALB/cCrg1 mice were exposed 16 hours after birth onwards to: 20 or 200 µg of 2′,4′,6′-trichloro-4-biphenylol [4′-OH-PCB-30]; 40 or 400 µg of 2′,3′,4′,5′-tetrachloro-4-biphenylol [4′-OH-PCB-61]; 10 µg of 4′-OH-PCB-30 plus 10 µg of 4′-OH-PCB-61, or 100 µg of 4′-OH-PCB-30 plus 100 µg of 4′-OH-PCB-61 (Martinez *et al.*, 2005). Exposure occurred via daily subcutaneous injections for 5 days and the mice were held for 20 months. [The neonatal mouse model has previously been used as a model for diethylstilbestrol-induced carcinogenesis after exposure in utero. The BALB/c mouse is known to be sensitive to the induction of cervicovaginal tumours by estrogens.] Significant treatment-related increases in the incidence of cervicovaginal tumours were observed for the groups treated with 4′-OH-PCB-30. Modest but statistically significant increases in the incidence of cervicovaginal tumours were also seen in both groups exposed to 4′-OH-PCB-61, and to the combination of 4′-OH-PCB-30 + 4′-OH-PCB-61 at the higher dose. There was also a significant effect of 4′-OH-PCB-61 at the lower dose on the incidence of carcinoma of the mammary gland.

Table 3.12 Study of carcinogenicity in mice exposed perinatally to 2′,4′,6′-trichloro-4-biphenylol (OH-PCB-30) and/or 2′,3′,4′,5′-tetrachloro-4-biphenylol (4′-OH-PCB-61)

Strain (sex) Duration Reference	Dosing regimen, Animals/group at start	For each target organ: incidence of tumours	Significance	Comments
BALB/cCrgl (F) Up to 20 mo Martinez *et al.* (2005)	Daily subcutaneous injections of 20 µL for 5 days starting 16 hours after birth. Mice were weaned at age 21 days. Examination daily for premature vaginal opening for the first 35 days of life and checks monthly to detect concretions. When concretions were found, the mice were removed from the study. All mice that survived to age 20 mo were killed Groups were injected with: sesame oil vehicle (control); 20 µg OH-PCB-30; 200 µg OH-PCB-30; 40 µg OH-PCB-61; 400 µg OH-PCB-61; 10 µg OH-PCB-30 + 10 µg OH-PCB-61; or 100 µg OH-PCB-30 + 100 µg OH-PCB-61 Number/group, NR	Cervicovaginal tract carcinoma: 0/33, 2/33, 10/22**, 4/30*, 5/24*, 3/36, 8/21* Mammary gland carcinoma: 0/33, 5/33, 0/22, 4/30*, 1/24, 3/36, 0/21	*$P < 0.05$ (Fisher exact test) **$P < 0.01$ (Fisher exact test)	Purity, NR The BALB/c mouse is sensitive to the induction of cervicovaginal tumours by estrogens. The inbred BALB/cCrgl strain has a low incidence of tumours of the mammary gland. The neonatal mouse model has previously been used as a model for diethylstilbestrol-induced carcinogenesis after exposure in utero Carcinomas of the cervicovaginal tract were mainly squamous cell carcinomas and adenosquamous carcinomas

F, female; mo, month; NR, not reported; PCB, polychlorinated biphenyl

3.3 Initiation–promotion and co-carcinogenicity studies

See Table 3.13

3.3.1 Initiation–promotion studies

(a) PCB-153

A study was carried out to determine whether PCB-153 had promoting activity in NDEA-initiated tumours of the liver in male B6129SF2/J mice, and whether the deletion of the NF-κB p50 subunit influenced liver carcinogenesis (Glauert *et al.*, 2008). Four groups of 14–17 wildtype and transgenic mice were injected intraperitoneally with NDEA (90 mg/kg bw in saline) at 9 weeks of age. After a 2-week recovery period, both wildtype and NF-κB $p50^{-/-}$ mice were injected intraperitoneally with PCB-153 at a dose of 0 (corn oil) or 300 µmol/kg bw every 14 days for a total of 20 injections. Mice were then maintained for an additional 15 weeks before being killed. Hepatocellular tumours were mainly classified as hepatocellular carcinoma. The incidence of hepatocellular tumours was higher in wildtype mice treated with PCB-153 than in wildtype mice receiving corn oil only. The deletion of p50 decreased the incidence of hepatocellular tumours in mice treated with PCB-153 or corn oil only.

(b) Aroclor 1254

(i) Mouse

In a study to determine whether Aroclor 1254 promoted the induction of liver nodules after initiation with NDEA, groups of male CD-1 mice were first given drinking-water containing NDEA at a dose of 0 or 8 µg/g bw per day, for 8 weeks (Gans & Pintauro, 1986). After 2.5 weeks, mice were given Aroclor 1254 as an intraperitoneal dose at 0 (tricaprylin/corn oil, 1/4, v/v) or 100 µg/g bw, every second week for 8 (8 mice per group) or 16 (18–19 mice per group) weeks. Aroclor 1254 did not increase the incidence of liver nodules, which were made up of type I, type II, or more commonly a mixture of type I and type II tissues. [The Working Group noted that it was not clear whether the diagnosis referred to hyperplasia and adenoma, respectively.]

Diwan *et al.* (1994) examined whether Aroclor 1254 promoted NDEA-initiated tumours of the liver in groups of 30 male DBA/2NCr × C57BL/6NCr (D2B6F1) mice. At age 5 weeks, mice were injected intraperitoneally with NDEA at a dose of 0 (tricaprylin vehicle) or 90 mg/kg bw. At age 7 weeks, mice were fed Aroclor 1254 at a dietary concentration of 175 or 350 mg/kg. The authors estimated the dose to be 0.1 or 0.2 mmol/kg bw per day based on a diet consumption of 4.5 g/day. [It was not reported whether food intake was measured.] Mice were killed after 60 weeks. The incidence of hepatocellular adenoma or carcinoma (combined) was significantly increased in both groups receiving NDEA plus Aroclor 1254 (all tumours were carcinomas) compared with the group receiving NDEA only (all tumours were adenomas). The incidences of hepatoblastoma in the group receiving Aroclor 1254 at 175 mg/kg, and of metaplastic and neoplastic glandular lesions within hepatocellular neoplasms (cholangiocellular neoplasms) in the groups receiving Aroclor 1254 at 175 and 350 mg/kg were higher [$P < 0.01$] than in the group receiving NDEA only.

Beebe *et al.* (1995) examined the promoting activity of Aroclor 1254 in the lung and liver in three strains of male mice that differ in AhR responsiveness: C57BL/6, DBA/2NCr, and B6D2F1. At age 5 weeks, groups of 23–34 mice were injected intraperitoneally with NDEA at a dose of 0 (tricaprylin vehicle) or 90 mg/kg bw. At age 8 weeks, the mice were placed on a diet containing Aroclor 1254 at a concentration of 0 or 100 mg/kg for 20 weeks. They were then left untreated for 24 weeks until being killed at age 52 weeks. Tumours of the liver were classified as hepatocellular adenoma, hepatocellular

DIPN, *N*-nitroso diisopropanolamine; DMBA, 7,12-dimethylbenz[*a*]anthracene; EHEN, *N*-ethyl-*N*-hydroxyethylnitrosamine; i.p., intraperitoneal; MDAB, 3′-methyl-4-dimethylaminoazobenzene; MNNG, *N*-methyl-*N*'-nitrosoguanidine; mo, month; MNU, *N*-methyl-*N*-nitrosourea; NDEA, *N*-nitrosodiethylamine; NDMA, *N*-nitrosodimethylamine; NNK, 4-(*N*-nitrosomethylamino)-1-(3-pyridyl)-1-butanone; NR, not reported; NS, not significant; PCB, polychlorinated biphenyl; PCDF, polychlorinated dibenzofuran; PeCDF, 2,3,4,7,8-pentachlorodibenzofuran; s.c., subcutaneous; TCDD, 2,3,7,8-tetrachlorodibenzo-*para*-dioxin; TPA, 12-*O*-tetradecanoylphorbol-l3-acetate; UN, unilateral nephrectomy; wk, week

carcinoma, cholangioadenoma, cholangiocarcinoma, or hepatoblastoma. [The classification of tumours of the lung was not described.] In NDEA-treated DBA/2NCR mice and B6D2F1 mice, Aroclor 1254 did not affect the incidence or multiplicity of tumours of the liver (all or any of the various types) when compared with mice receiving NDEA only. In NDEA-treated C57BL/6 mice, Aroclor 1254 increased the incidences of tumours of the liver (all types combined) and of hepatocellular adenoma. The incidence or multiplicity of tumours of the lung was not affected by treatment with NDEA and Aroclor 1254 in any strain when compared with mice receiving NDEA only.

Poland *et al.* (1982) investigated whether Aroclor 1254 could promote *N*-methyl-*N*′-nitro-*N*-nitrosoguanidine (MNNG)-initiated skin papillomas in female HRS/1 hairless mice. At age 8 weeks, mice were given 5 µmol of MNNG (in 50 µl of acetone) or the vehicle topically. Mice were then given a topical application of 1 mg of Aroclor 1254 (in 50 µl of acetone) per mouse, twice per week, for 20 weeks. There were 20 mice in the groups receiving MNNG plus Aroclor 1254, or Aroclor 1254 only, and 26 in the MNNG only-treated group. Aroclor 1254 did not promote MNNG-initiated tumours, and there was no neoplastic effect of Aroclor 1254 in non-initiated mice. [The statistical test was not reported.]

Beebe *et al.* (1993) investigated whether Aroclor 1254 could promote tumours of the lung and liver initiated by NDMA or 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK), either neonatally or transplacentally, in male and female Swiss (Cr:NIH) mice. For transplacental studies, pregnant mice were injected intraperitoneally with NNK at a dose of 0 (saline vehicle) or 100 mg/kg bw on days 15, 17, and 19 of gestation, or with NDMA at a dose of 0 (saline vehicle) or 10 mg/kg bw on day 19 of gestation. For the neonatal studies, infant mice were injected with NDMA (5 mg/kg bw), NNK (50 mg/kg bw), or saline vehicle on postnatal day 4. Mice were then given Aroclor 1254 by gavage (500 mg/kg bw) or olive oil vehicle for 44 weeks starting at age 56 days. There were 27–30 mice in all groups when the mice were killed at age 52 weeks. In females, transplacental exposure to NNK or NDMA plus Aroclor 1254 did not increase the incidence of tumours of the lung or liver compared with controls treated with NNK or NDMA only. In males, Aroclor 1254 increased the incidence of tumours of the lung (but not of the liver) initiated by either NDMA or NNK transplacentally. In females, Aroclor 1254 increased the incidence of tumours of the lung initiated neonatally by NNK, but not by NDMA. In males, Aroclor 1254 increased the incidence of tumours of the lung initiated neonatally by NDMA, but not by NNK. [The classification of tumours of the lung was not provided.]

(ii) Rat

Preston *et al.* (1981) investigated whether Aroclor 1254 promotes chemically-induced hepatocarcinogenesis in male Sprague-Dawley rats. Three groups of 40 rats were first given drinking-water containing NDEA at a concentration of 66 µg/mL for 5 weeks as an initiating agent. The rats were then fed an unrefined diet containing Aroclor 1254 at a concentration of 100 mg/kg, or Aroclor 1254 from which PCDFs (present as impurities) had been removed, or control diet. Rats were fed the diets for 18 weeks and then killed. Lesions of the liver were classified as foci of cellular alteration, neoplastic nodules, hepatocellular carcinoma, cholangioma, or cholangiocarcinoma. The administration of either Aroclor 1254, or Aroclor 1254 without PCDFs, significantly increased the incidences of NDEA-initiated hepatocellular carcinoma.

Vansell *et al.* (2004) studied whether Aroclor 1254 could promote tumours of the thyroid initiated by *N*-nitrosodiisopropanolamine (DIPN) in male Sprague-Dawley rats. Rats were first injected subcutaneously with DIPN at 0 (saline) or 2.5 g/kg bw. After a 1-week recovery period,

rats were fed a diet containing Aroclor 1254 at a concentration of 100 mg/kg for 19 weeks and then killed. Tumours were classified as thyroid cystic adenoma, thyroid follicular adenoma, thyroid follicular carcinoma, or "thyroid complete carcinoma." Aroclor 1254 only significantly increased the incidence of "thyroid complete carcinoma." [The Working Group noted the uncertainty of the classification of one type of thyroid tumour as "thyroid complete carcinoma."]

(c) Kanechlor 400 and Kanechlor 500

Rat

Kimura *et al.* (1976) gave female Donryu rats (age, 11–15 weeks) diets containing Kanechlor 400 or 3′-methyl-4-dimethylaminoazobenzene (MDAB) at a concentration of 400 or 600 mg/kg, respectively. Both agents were dissolved in olive oil before being added to the diet. There were five groups of 25 rats each. A first group was treated with Kanechlor 400 for 6 months, no treatment for 2 months, and then MDAB for 2 months; a second group was treated with MDAB for 2 months, no treatment for 2 months, then Kanechlor 400 for 6 months; a third group was treated with Kanechlor 400 for 6 months with MDAB given for the last 2 months, and no treatment for 4 months; a fourth group was treated with MDAB for 2 months and no treatment for 8 months; and a fifth group treated with Kanechlor 400 for 6 months and no treatment for 4 months. Additionally a sixth group of 10 rats was maintained for 10 months with no treatment. In all groups except that given MDAB only, body weight decreased markedly compared with untreated controls. Therefore, treatment with Kanechlor 400 was discontinued for 2 weeks after 3 months of treatment, and again for 4 weeks after the second 1 month of treatment. As for survival, 9, 11, 11, 15, 12 and 7 mice remained in groups 1 to 6, respectively. Only 2 out of 15 mice receiving MDAB only developed hepatocellular carcinoma compared with 7 out of 11 mice receiving MDAB followed by Kanechlor 400 [$P < 0.05$]. [The Working Group noted that the authors calculated the incidence in the group receiving MDAB then Kanechlor 400 compared to all other groups using a *t*-test, but it is not correct to use this test for binomial data.]

In a study to determine whether Kanechlor 500 could promote NDEA-initiated carcinogenesis, groups of 7–8 male Wistar rats were given drinking-water containing NDEA at a concentration of 50 mg/L for 2 weeks (Nishizumi, 1979). After a 1-week recovery period, the rats were given Kanechlor 500 (0.1 mL of 10% Kanechlor 500 in olive oil) by gavage twice per week for 12 weeks. Rats were then maintained without further treatment until being killed 40 and 52 weeks after the start of the experiment. Data were analysed using the Student *t*-test. The incidence [$P < 0.05$] and tumour multiplicity ($P < 0.01$) of hepatocellular tumours (mainly hepatocellular carcinomas) was significantly higher in rats given NDEA plus Kanechlor 500 than in rats given NDEA only, at both 40 and 52 weeks.

(d) Unspecified PCBs

Rat

In a study to examine the effect of an unspecified PCB mixture on hepatic and renal carcinogenesis induced by *N*-ethyl-*N*-hydroxyethylnitrosamine (EHEN), two groups of 20–21 male Fischer 344 rats were given drinking-water containing 0.1% EHEN for 2 weeks, or untreated drinking-water (Hirose *et al.*, 1981). After an unspecified time, rats were placed on a diet containing 0.05% PCBs [not further specified] for 32 weeks. One week after starting the experimental diet, the right kidney was removed (unilateral nephrectomy). All rats treated with EHEN plus PCBs (19 out of 19; $P < 0.001$) developed hepatocellular carcinoma, compared with one third (7 out of 21) of the rats treated with EHEN only. Treatment with PCBs had no effect on the incidence or number of EHEN-induced

tumours of the kidney (neoplastic nodules or renal cell tumours [all benign tumours]) compared with rats receiving EHEN only. No renal cell carcinoma was observed.

In a study to determine whether an unspecified PCB mixture could promote tumours of the liver and kidney induced by NDMA, four groups of 20 male Fischer 344 rats were fed a diet containing 0.04% NDMA for 2 weeks (Arai *et al.*, 1983). After a 2-week recovery period, rats were fed a diet containing PCBs [not further specified] at a concentration of 0 (basal diet) or 500 mg/kg for 28 weeks and then killed. In some groups, unilateral nephrectomy was performed at 5 weeks (1 week after starting the PCB containing diet). Tumours of the liver were classified as hyperplastic and neoplastic nodules, and hepatocellular carcinoma. Tumours of the kidney were classified as adenoma, adenocarcinoma, and nephroblastoma. In rats receiving NDMA plus PCBs, the incidences of liver hyperplastic or neoplastic nodules (combined) and of hepatocellular carcinoma (only in non-nephrectomized rats) were higher than in the respective controls. The administration of PCBs, either with or without nephrectomy, decreased the incidence of nephroblastoma. [The Working Group noted that no statistical analysis was reported and that there appeared to be significant mortality in some groups, especially in the group receiving NDMA plus PCBs plus unilateral nephrectomy.]

3.3.2 Studies with other modifying agents

(a) PCB-77

Rat

Nesaretnam *et al.* (1998) investigated whether dietary fat could influence the effect of PCB-77 on DMBA-induced tumours of the mammary gland in female Sprague-Dawley rats. Groups of 20 female rats were given DMBA (10 mg in 0.5 mL corn oil) by gavage at age 50 days. Two groups were also given a simultaneous dose of PCB-77 at 10 mg/kg bw by gavage, then a diet containing PCB-77 at a concentration of 500 µg/g corn oil for an additional week. Two groups were not exposed to PCB-77. [It was unclear whether these rats were given the vehicle instead of PCB-77.] The four groups (treated and not treated with PCB-77) were then fed either a low-fat (5%) or a high-fat (20%) purified diet. [Fat was substituted for dextrose on a weight basis rather than on a caloric basis.] Rats were palpated weekly for tumours of the mammary gland and were killed 10.5 weeks after administration of DMBA. Tumours at autopsy were mainly classified as mammary ductal carcinoma. The number of palpable tumours of the mammary gland was significantly higher in rats fed a high-fat diet plus PCB-77 than in rats fed a high-fat diet only, at 8, 9, and 10 weeks. Similarly, the incidence of tumours of the mammary gland was higher in rats fed a low-fat diet plus PCB-77 (~60%) than in rats fed a low-fat diet (~15%) only, at 10.5 weeks. [Data were presented graphically.]

(b) Aroclor 1254

Mouse

Smith *et al.* (1990) investigated whether iron (Fe) and/or Aroclor 1254 could influence liver carcinogenesis in male C57BL/10ScSn and DBA/2 mice. Mice (age 7–10 weeks) were first injected subcutaneously with Imferon, an Fe–dextran complex (12 mL/kg; dose of Fe, 600 mg/kg bw) or an equivalent volume of dextran C solution in water (200 mg/mL). After 7 days, mice were fed a diet mixed with 2% corn oil containing Aroclor 1254 at a concentration of 100 mg/kg for 2 (5 mice/group), 4 (C57 only, 5 mice/group), 8 (C57, 10 mice/group; DBA, 5–7 mice/group), or 12 months (C57 only, 15–19 mice/group) before being killed. Tumours were classified as hepatocellular adenoma or hepatocellular carcinoma. Higher incidences of hepatocellular tumour were observed in C57 mice receiving both Fe and Aroclor 1254 at 8 months (adenomas) and 12

months (adenomas and carcinomas) compared with those receiving Aroclor 1254 only. [No statistical analyses were reported.]

Smith *et al.* (1995) studied the influence of Fe and/or Aroclor 1254 on liver carcinogenesis in male C57BL/10ScSn mice [age of mice not reported]. Mice were subcutaneously injected a Fe–dextran solution (100 mg/mL Fe, and 100 mg/mL dextran; dose of Fe, 600 mg/kg bw) or the equivalent dextran solution only. After 3 days or 1 week, mice were fed a diet containing Aroclor 1254 (0.01% of diet) and corn oil (2%) for 8 months (10 mice/group) or 12 months (15–19 mice/group). Tumours were classified as nodules [hepatocellular adenoma] or hepatocellular carcinoma. Higher incidences of hepatocellular tumours were observed in mice receiving Aroclor 1254 plus Fe for 8 months (adenomas) and 12 months (adenomas and carcinomas) than in mice receiving Aroclor 1254 only. [No statistical analyses were reported.]

Greaves *et al.* (2005) studied the effects of deletion of the *Cyp1a2* gene on the induction of tumours of the liver by Aroclor 1254 and Fe in male C57BL/6J mice. *Cyp1a2* knockout $^{(-/-)}$ and wildtype $^{(+/+)}$ mice were given a Fe–dextran solution (Fe, 800 mg/kg bw) [route not reported], followed by a diet containing Aroclor 1254 at 100 mg/kg for 57 weeks or until death. There were 10 mice in the Aroclor 1254-treated groups and 5 mice in the control groups receiving Fe only. Liver tumours were classified as adenomas. No tumours were observed in *Cyp1a2* $^{(-/-)}$ mice or in *Cyp1a2* $^{(+/+)}$ wildtype mice not receiving Aroclor 1254. No tumours were seen in the 10 *Cyp1a2* $^{(-/-)}$ mice receiving Aroclor 1254, but 5 out of 10 [not significant] of the wildtype mice receiving Aroclor 1254 developed liver adenoma. [No statistical analyses were provided.]

(c) Kanechlor 400 and Kanechlor 500

Mouse

Nakanishi *et al.* (2001) examined the effects of Kanechlor 400 on lung tumorigenesis induced by 1-nitropyrene in male A/J mice. Mice (age, 6 weeks) were given a single intraperitoneal dose of Kanechlor 400 at 0 (corn oil vehicle) or 2.5 mg/kg bw. Mice were then given 1-nitropyrene or the DMSO vehicle, three times per week (17 intraperitoneal injections for a total dose of 1575 mg/kg bw). Mice were killed 18 weeks after the last injection of 1-nitropyrene. Numbers of mice per group were as follows: DMSO controls, 8; Kanechlor 400, 10; 1-nitropyrene, 20; 1-nitropyrene plus Kanechlor 400, 13. Lung lesions were classified as bronchioloalveolar hyperplasia, adenoma, or adenocarcinoma. The incidence of lesions of the lung was increased in both groups of mice receiving 1-nitropyrene. The average number of lesions, but not incidence, was significantly greater in the group receiving Kanechlor 400 plus 1-nitropyrene than in the group receiving 1-nitropyrene only.

Nagasaki *et al.* (1975) investigated whether co-administration of Kanechlor 400 or Kanechlor 500 and α-benzene hexachloride (α-BHC) [hexachlorocyclohexane] would affect the incidence of nodular hyperplasia of the liver and hepatocellular carcinoma in male dd mice. Mice were given diets containing α-BHC at a concentration of 50, 100, or 250 mg/kg, and/or Kanechlor 400 or Kanechlor 500 (100 or 250 mg/kg), for 24 weeks. Nodular hyperplasia and hepatocellular carcinoma were observed. The incidence of hepatocellular carcinoma was higher [$P < 0.05$] in mice receiving 250 mg/kg α-BHC and the higher dose of Kanechlor 400 or Kanechlor 500, than in mice receiving only α-BHC at 250 mg/kg. No tumours were induced by Kanechlor 400 or Kanechlor 500 only. [Statistical analyses were not reported.]

A study by Ito *et al.* (1973) examined the effects of co-administration of Kanechlor 500 and one isomer of benzene hexachloride (BHC)

[hexachlorocyclohexane] on the incidence of nodular hyperplasia of the liver and hepatocellular carcinoma. Groups of male dd mice (age, 8 weeks) were given diets containing α-, β-, or γ-BHC (50, 100 or 250 mg/kg) for 24 weeks, with or without Kanechlor 500 (250 mg/kg). In some groups, Kanechlor 500 promoted the incidence of nodular hyperplasia and hepatocellular carcinoma induced by α-BHC and β-BHC. [Statistical analyses were not reported.]

(d) PCB-126, PeCDF, and TCDD

Rat

In a study by the NTP, groups of 81 female Harlan Sprague-Dawley rats were given a mixture of TCDD, PeCDF, and PCB-126 by gavage, 5 days per week, for up to 2 years (NTP, 2006e). Up to 10 rats per group were evaluated after 14, 31, and 53 weeks. Doses were formulated by using the WHO TEF values of 1.0 for TCDD, 0.1 for PCB-126, and 0.5 for PeCDF. Specific target doses were: "10 ng TEQ/kg bw" (TCDD, 3.3 ng/kg; PeCDF, 6.6 ng/kg; PCB-126, 33.3 ng/kg), "22 ng TEQ/kg bw" (TCDD, 7.3 ng/kg; PeCDF, 14.5 ng/kg; PCB-126, 73.3 ng/kg), "46 ng TEQ/kg bw" (TCDD, 15.2 ng/kg; PeCDF, 30.4 ng/kg; PCB-126, 153 ng/kg), and "100 ng TEQ/kg bw" (TCDD, 33 ng/kg; PeCDF, 66 ng/kg; PCB-126, 333 ng/kg). Rats in the control group received the corn oil : acetone vehicle (99 : 1; 2.5 mL/kg bw) only. After 2 years, there were statistically significant increases ($P < 0.001$) in the incidences of cholangiocarcinoma, hepatocellular adenoma, and cystic keratinizing epithelioma of the lung in the group at 100 ng TEQ/kg bw. The incidence of cholangiocarcinoma was also significantly increased ($P = 0.011$) in the group at 46 ng TEQ/kg. In addition, there was a significant trend in the incidence of these three types of neoplasm with increasing dose.

4. MECHANISTIC AND OTHER RELEVANT DATA

4.1 Absorption, distribution, metabolism, and excretion

In this Section, the most recent Ballschmiter & Zell (BZ) nomenclature was used throughout (see Mills *et al.*, 2007). For the full corresponding IUPAC nomenclature, the reader is referred to Section 1.1, Tables 1.1–1.3. For the methyl sulfonyl metabolites, and wherever the nomenclature reported is unclear, the name of the metabolite is given as reported in the article, followed by, where appropriate, the abbreviation as well as the structural name (Maervoet *et al.*, 2004; Grimm *et al.*, 2015).

4.1.1 Absorption

(a) Oral exposure

(i) Humans

The absorption of polychlorinated biphenyls (PCBs) was studied in four breastfed infants in Sweden by Dahl *et al.* (1995). Absorption was measured by comparing the estimated total intake and the excretion in faeces for 48 hours, at 1, 2, and 3 months postpartum. The concentrations of 56 congeners in maternal milk were determined. For tetrachlorosubstituted to octachlorosubstituted congeners, absorption was found to be close to 100%, while absorption of trichlorinated congeners was 60–98%, probably due to the low levels at which they were present and ensuing analytical difficulties in detection. [Another possible explanation could be metabolism of the trichlorinated congener.]

The gastrointestinal absorption of 10 congeners from food was investigated using a mass balance approach in seven individuals aged 24–81 years with different contaminant body burdens (Schlummer *et al.*, 1998). The difference between ingested and excreted amounts of the chlorinated compounds was defined as net absorption. Nearly complete net absorption was observed for PCB-28, PCB-52, PCB-77, PCB-101, and PCB-126. Absorption of PCB-105, PCB-138, PCB-153, and PCB-180 was > 60% in most volunteers, but limited absorption was observed in the three older subjects. In all cases, absorption of PCB-202 was < 52%.

(ii) Experimental systems

Several reports have been published on the dietary absorption of PCBs, mostly individual congeners. Gastrointestinal absorption of congeners with between one and six chlorine atoms has been investigated by monitoring faecal excretion in rats fed individual congeners at doses ranging from 5 to 100 mg/kg bw. Absorption of the administered dose was > 90% for all 20 congeners tested (Albro & Fishbein, 1972). Metabolic studies in rodents given oral doses of various radiolabelled PCBs with three to six chlorine atoms (i.e. PCB-31, PCB-47, PCB-85, PCB-101, and PCB-153) indicated that gastrointestinal

absorption was highest for the trichlorobiphenyl congener (about 94% of the administered dose), and lowest for the hexachlorobiphenyl PCB-153 (28%) (Bergman *et al.*, 1982). In a study by Tanabe *et al.* (1981), absorption efficiency was 95% for dichlorobiphenyls, but only 75% for octachlorobiphenyls. These data suggested that, in rats, absorption of PCBs decreases as the number of chlorine atoms increases.

(b) Inhalation

(i) Humans

There is indirect evidence for absorption of PCBs via inhalation in humans; several congeners have been detected in body fluids of people exposed in occupational settings or frequenting contaminated buildings, such as schools, where air concentrations of PCBs have also been measured (Wolff, 1985; Wolff *et al.*, 1992; Schwenk *et al.*, 2002; Liebl *et al.*, 2004).

(ii) Experimental systems

Hu *et al.* (2010) used a nose-only exposure system to assess the time course of PCB vapour uptake from commercial products in animals. Rats (average weight, 188 g) were exposed to vapours of Aroclor 1242 (PCB concentration, 2.4 mg/m^3; total amount, 40 µg) for a total of 2 hours, with a 1-hour break, and killed at 0, 1, 3, 6, and 12 hours after exposure. Congeners detected in tissues included mostly PCBs with mono- or di-*ortho*-substitution, ranging from mono- to pentachlorobiphenyls, with the majority being tri- and tetrachlorobiphenyls. PCB-20 + PCB-28 co-elution was most abundant in every tissue. When compared with the air mixture, most of the material retained in the tissues had shifted from mono- and dichlorinated PCBs to tri- and tetra- or even more highly chlorinated biphenyls. The amount of PCBs measured in the five tissues collected (liver, lung, blood, adipose tissue, and brain) was 5 µg per rat. The measured body burden (i.e. the sum of PCBs loaded at the end of exposure) was 33 µg per rat, suggesting pulmonary absorption of close to 100%. Casey *et al.* (1999) found that uptake of PCBs was greater by inhalation than by ingestion in a comparison of rats exposed to Aroclor 1254 for 30 days via inhalation (0.9 µg/m^3) or in the diet (0.436 µg/g).

(c) Dermal exposure

(i) Humans

Studies on exposure of capacitor workers to PCBs suggested that these compounds are well absorbed by skin contact (Wolff, 1985). Skin samples collected from human cadavers and exposed in vitro to [^{14}C]-labelled Aroclor 1254 and Aroclor 1242 retained 43–44% of the administered dose over a 24-hour period when the mixtures were formulated in water (Wester *et al.*, 1990, 1993). A lower retention was observed when PCBs were formulated in mineral oil or adsorbed on contaminated soil.

(ii) Experimental systems
