Standard Operating Procedure for Analysis of US EPA Geospatial Measurement of Air Pollution-Remote Emission Quantification by Direct Assessment (GMAP-REQ-DA) Method Data for Methane Emission Rate Quantification using the Point Source Gaussian Method

Scope: The following protocol describes procedures for analysis of data collected with the US EPA Geospatial Measurement of Air Pollution-Remote Emission Quantification–Direct Assessment (GMAP-REQ-DA) technique to yield methane emission rates using the Point Source Gaussian (PSG) method. This protocol provides guidance on preparing input data files for use with the PSG software program, importing the input files into the software, and instructions for processing the data.

Purpose: To provide specific guidance on analyzing data collected with the GMAP-REQ-DA technique to yield methane emission rates using the PSG method.

1.0 Overview

The US EPA Geospatial Measurement of Air Pollution-Remote Emission Quantification by Direct Assessment (GMAP-REQ-DA) mobile measurement system has been developed as a tool to assess emissions of air pollutants from distributed point sources. The system consists of a fast-response methane analyzer, global positioning system (GPS), and wind monitors, installed in a measurement vehicle. The integrated system uses customized software to control operation of instrumentation, and acquisition of data. The system has been previously deployed to assess emissions at upstream oil and gas production sites, but has utility for monitoring emissions from other emission sources. During the measurement campaigns, the system is deployed to assess emissions from multiple potential sources, on a site-by-site basis.

Data elements collected with the GMAP-REQ-DA technique include target analyte concentration, GPS data, 3-D Sonic Anemometer data, and AIO Compact Weather Station data. The GMAP-REQ-DA data elements are used to calculate total site emission rates. The current document describes the procedures for calculating methane emission rates using the Point Source Gaussian (PSG) approach. The PSG approach utilizes a MATLAB®-based analysis program developed by EPA ORD NRMRL and ARCADIS. The program is used to pre-process raw data collected during the measurement surveys, create data input files for the PSG algorithm, and to calculate methane emission rate estimates from the survey sites. Section 2.0 of this document presents details on the PSG

algorithm, and Section 3.0 provides procedures for using the analysis software for calculating emission rates. Section 4.0 describes a quality-assurance tool used to assess the location of detected emission sources.

2.0 Point Source Gaussian Emission Quantification Method

Prior to analysis of raw data collected in the field, the MATLAB®-based Point Source Gaussian analysis program is used to pre-process the data. The first step in pre-processing the data is to time-align the raw data to correct for the delay time it takes for the sample to reach the analyzer through the sampling line. The exact delay time is determined by conducting delay tests in the field as part of the in-field calibration checks. The delay time will vary slightly for each site, so the response tests should be conducted on the first day of each measurement campaign. After the delay time has been determined, it is input to the analysis software, and the software performs the time alignment correction (instructions for inputting the delay time to the analysis software are discussed in Section 3).

The second step in pre-processing the data is to rotate the 3-D Sonic Anemometer data to streamlined coordinates. The anemometer outputs velocity data in the *u, v*, and *w* coordinates. The coordinate system is first rotated through the angle formed by the average wind velocity in the *u* and *v* directions, as shown in Equation 1 below:

$$\theta_1 = \tan^{-1}\left(\frac{avg\ u}{avg\ v}\right) \tag{1}$$

The rotated average velocity values (*u', v'*) from the original coordinate system are calculated using the following rotation matrix:

$$\begin{bmatrix} v' \\ u' \end{bmatrix} = \begin{bmatrix} \cos(\theta_1) & \sin(\theta_1) \\ -\sin(\theta_1) & \cos(\theta_1) \end{bmatrix} \begin{bmatrix} v \\ u \end{bmatrix} \tag{2}$$

The coordinate system is then rotated through the angle formed by the average wind velocity in the *v* and *w* directions:

$$\theta_2 = \tan^{-1}\left(\frac{avg\ w}{avg\ v'}\right) \tag{3}$$

The rotated average velocity values (*v", w'*) are calculated using the following rotation matrix:

$$\begin{bmatrix} v'' \\ w' \end{bmatrix} = \begin{bmatrix} \cos(\theta_2) & \sin(\theta_2) \\ -\sin(\theta_2) & \cos(\theta_2) \end{bmatrix} \begin{bmatrix} v' \\ w \end{bmatrix} \tag{4}$$

SOP for Analysis of US EPA GMAP-REQ-DA Method Data for Methane
Emission Rate Quantification using the Point Source Gaussian Method
SOP 601 for OTM 33A
September 2013 (Revision 0)
Page 6 of 64

In the revised coordinate system, $v^{''}=v; \; u^{'}=u; \; w^{'}=w$

The rotated wind speed value is expressed as:

$$WS=\sqrt{v^2+u^2} \tag{5}$$

The rotated 3-dimensional azimuthal wind direction is expressed as:

$$WD=180+\left[a\tan 2\left(\frac{avg\ u}{avg\ v}\right)*\frac{180}{\pi}\right] \tag{6}$$

The rotation calculations are performed automatically by the analysis software after the raw data files are input to the program.

After pre-processing has been completed, the software is used to determine the local stability class of wind conditions during the time of the stationary measurements. The local wind stability class is determined by the analysis software using the standard deviation of 2-dimensional wind direction and turbulent intensity (ratio of the standard deviation of the wind speed to the average wind speed). When determining the local wind stability class based on the standard deviation of 2-dimensional wind direction (*StdWD*), the following relationships are used:

$Stability\ Class=1\ if\ Std\ WD>27.50°$
$Stability\ Class=2\ if\ 23.50°<Std\ WD\le27.50°$
$Stability\ Class=3\ if\ 19.50°<StdWD\le23.50°$
$Stability\ Class=4\ if\ 15.50°<StdWD\le19.50°$
$Stability\ Class=5\ if\ 11.50°<StdWD\le15.50°$
$Stability\ Class=6\ if\ 7.50°<StdWD\le11.50°$
$Stability\ Class=7\ if\ StdWD\le7.50°$

When determining the local wind stability class based on the turbulent intensity (*turbuint*), the following relationships are used:

$Stability\ Class=1\ if\ turbu\int>0.205$
$Stability\ Class=2\ if\ 0.180<turbu\int\le0.205$
$Stability\ Class=3\ if\ 0.155<turbu\int\le0.180$
$Stability\ Class=4\ if\ 0.130<turbu\int\le0.155$
$Stability\ Class=5\ if\ 0.105<turbu\int\le0.130$
$Stability\ Class=6\ if\ 0.08<turbu\int\le0.105$
$Stability\ Class=7\ if\ turbu\int\le0.080$

Page 7 of 64

The average local wind stability class (*pgi*) is defined as the average of the stability class determinations based on the standard deviation of 2-dimensional wind direction and the turbulent intensity parameter. The average local wind stability class for a particular stationary survey is classified using the following table, where Class 1 represents extremely unstable wind conditions, and Class 7 represents extremely stable wind conditions.

$Stability\,Class = 1\ if\ pgi < 1.5$

$Stability\,Class = 2\ if\ 1.50 \leq pgi < 2.5$

$Stability\,Class = 3\ if\ 2.50 \leq pgi < 3.50$

$Stability\,Class = 4\ if\ 3.50 \leq pgi < 4.50$

$Stability\,Class = 5\ if\ 4.50 \leq pgi < 5.50$

$Stability\,Class = 6\ if\ 5.50 \leq pgi < 6.50$

$Stability\,Class = 7\ if\ pgi \geq 6.50$

After the local wind stability class has been determined, the values of horizontal (σ_y) and vertical (σ_z) dispersion are determined from point source dispersion tables using the measured source distance and the determined average local wind stability class. The tables used for determining the values of σ_y and σ_z are presented in Appendix A of this document.

Next, the analysis software determines the average background methane concentration by calculating the average of the lowest 5% of all methane concentration values collected during the survey. The background concentration value is then subtracted from all concentration data collected during the survey. The concentration data are then sorted into 5-degree incremental bins based on wind direction during the time of the measurements, and the average methane concentration for each bin is calculated. The plot of concentration versus wind direction is then fitted to a Gaussian function during the stationary survey. Prior to performing the Gaussian fit, the software utilizes a "cut filter" value of 2%. In this approach, data from a particular bin are removed from the analysis if the total number of data points in any particular bin is not greater than 2% of the total number of data points collected during the survey. The peak value of the Gaussian fit is the peak methane concentration (*a1* parameter), which is used in the calculation of plane-integrated methane concentration. Figure 1 below presents an example plot of methane concentration data as a function of prevailing wind direction, fitted using a Gaussian function. The plot shows the determined *a1* value as 2.53 ppm.

Emission Rate Quantification using the Point Source Gaussian Method
SOP 601 for OTM 33A
September 2013 (Revision 0)
Page 8 of 64
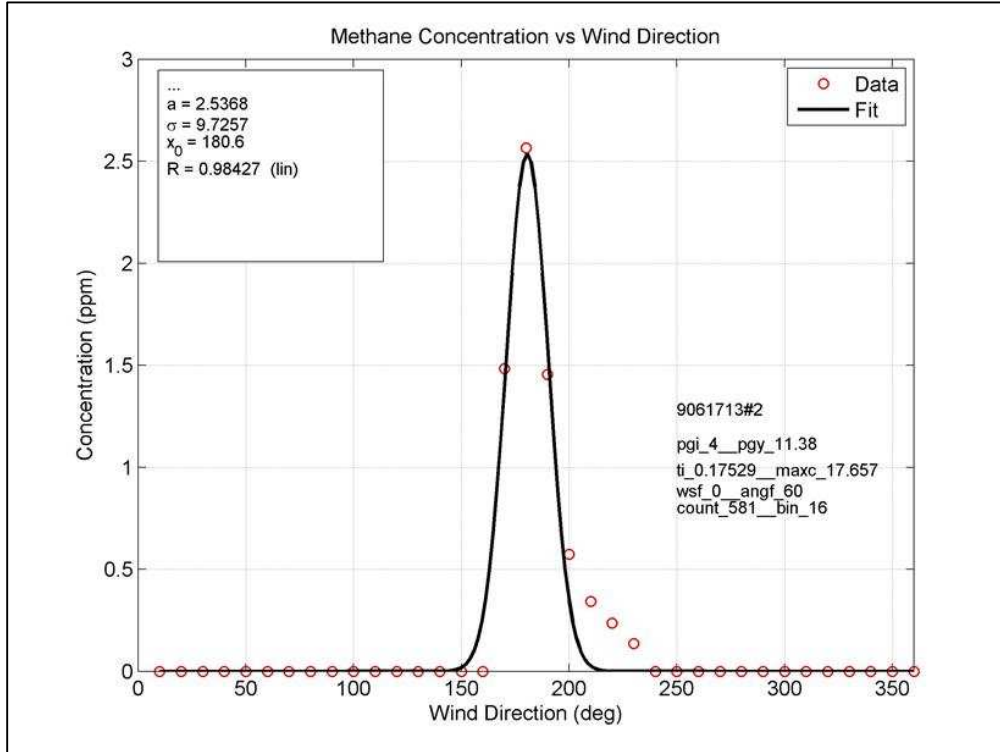

Figure 1. Gaussian Fit of Methane Concentration as a Function of Wind Direction

After the peak methane concentration (**a1**) has been determined, it is converted from units of ppmv to units of grams per cubic meter. The plane-integrated methane concentration is then determined using the following two-dimensional Gaussian integration:

$$G(y,z) = a1 \times \iint \exp - \left(\frac{(y)^2}{2\sigma_y^2} + \frac{(z)^2}{2\sigma_z^2} \right) = 2\pi \times a1 \times \sigma_y \times \sigma_z \qquad (7)$$

Where:

    y= crosswind distance (m)

    z= vertical distance (m)

    a1= peak average methane concentration (g/m^3) as determined by Gaussian fit

    σ_y = standard deviation of the crosswind plume concentration (m)

    σ_z = standard deviation of the vertical plume concentration (m)

Page 9 of 64

This expression is multiplied by the calculated wind speed during the survey (determined using Equation 5) to yield the estimated emission rate (in grams per second) of the target compound.

3.0 Utilizing the Point Source Gaussian Method to Calculate Emission Rates

The PSG approach utilizes a MATLAB®-based analysis program developed by EPA ORD NRMRL and ARCADIS. The program, called *PG_Analysis_Methane_CSV*, is utilized to perform all of the pre-processing steps described in Section 2.0, and calculate the emission flux in g/s from a given source located a certain distance away from the measurement location. The program is also capable of reading .csv files in the U.S. EPA Retigo format. The *PG_Analysis_Methane_CSV* program code is presented in Appendix B of this document.

3.1 Converting Raw Data Output Files

Prior to executing the *PG_Analysis_Methane_CSV* software, the raw data output files created by the GMAP-REQ-DA data acquisition software (ST files) for each site survey from a particular measurement campaign must be converted from .tdms format, to STR files in .csv format. The file conversion is done utilizing the *TDMS to CSV TranslatorRev 1.2.2. Build 5/28/2013* program. Data files are converted using the following steps:

1. Open the *TDMS to CSV TranslatorRev 1.2.2. Build 5/28/2013* program. The program main screen will be displayed.

2. Select the data file to be converted by clicking the "browse" icon, located to the right of the "Path to Single File" box in the program main screen. Select the desired file and hit OK as shown in Figure 2.

September 2013 (Revision 0)
Page 11 of 64
Figure 2. File Translator Program Main Screen Showing Selection of File for Conversion

1. Under the "Field Code", enter the name of the field study.

2. Click on the "Translate Single File" tab located in the top right corner of the main screen, as shown in Figure 2.

3. The program will begin creating a new STR file in .csv format for each site survey from the particular measurement campaign. After the new file has been created, a confirmation message will appear in the "Results" box on the program main screen, as shown in Figure 3. The new file is created in the same folder as the original .tdms file.

Page 12 of 64
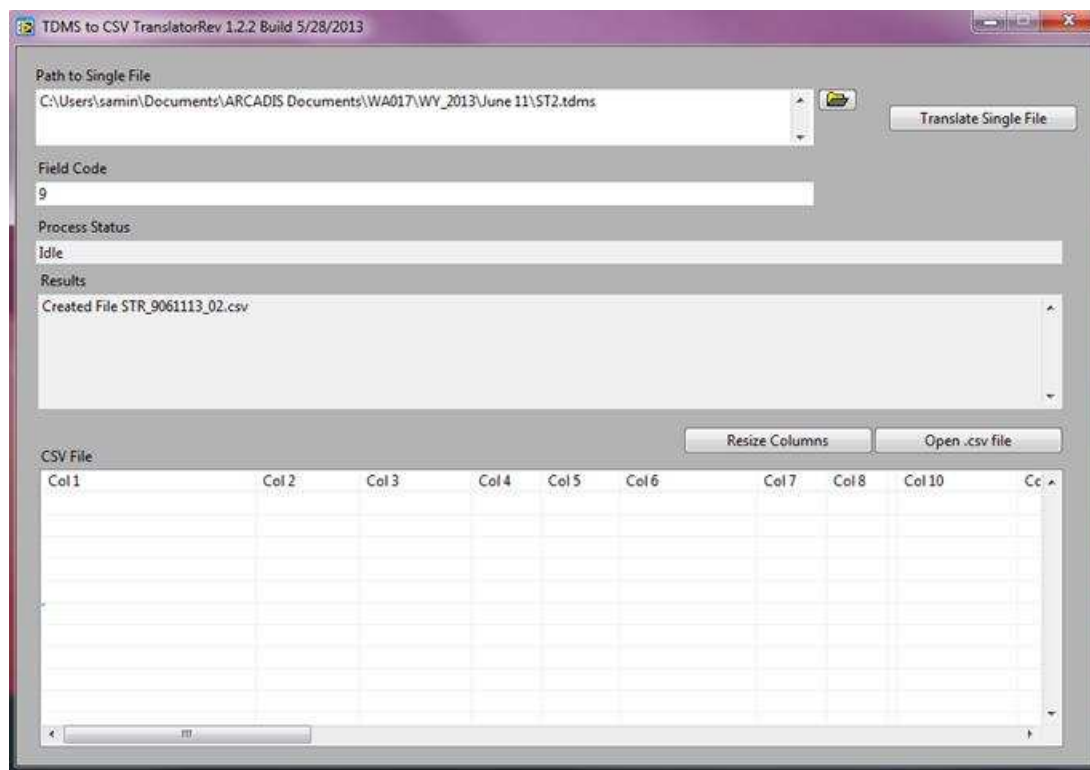

Figure 3. File Translator Program Main Screen Showing Confirmation of File Conversion

An example STR data output file in .csv format is shown in Appendix C of this document.

3.2 Initializing the *PG_Analysis_Methane_CSV* Program for Emissions Calculations

After all raw data output files from a field study have been converted to STR files in .csv format, create a project folder on the C: drive of the computer being used for data analysis. The folder can be labeled using any name convenient to identify the measurement project. Create a subfolder within the project folder named "Analysisfiles". Copy and paste all converted .csv STR files into the "Analysisfiles" subfolder. The subfolder should also contain the *PG_Analysis_Methane_CSV* MATLAB® code to analyze the data, and all the associated files necessary to run the *PG_Analysis_Methane_CSV* program.

Prior to initiating the program to calculate emission rates, it is necessary to input several parameters that the program uses in the emission calculation. These parameters are input to a user input spreadsheet, *Parameter.xls*, shown in Figure 4.

SOP for Analysis of US EPA GMAP-REQ-DA Method Data for Methane
Emission Rate Quantification using the Point Source Gaussian Method
SOP 601 for OTM 33A
September 2013 (Revision 0)
Page 13 of 64
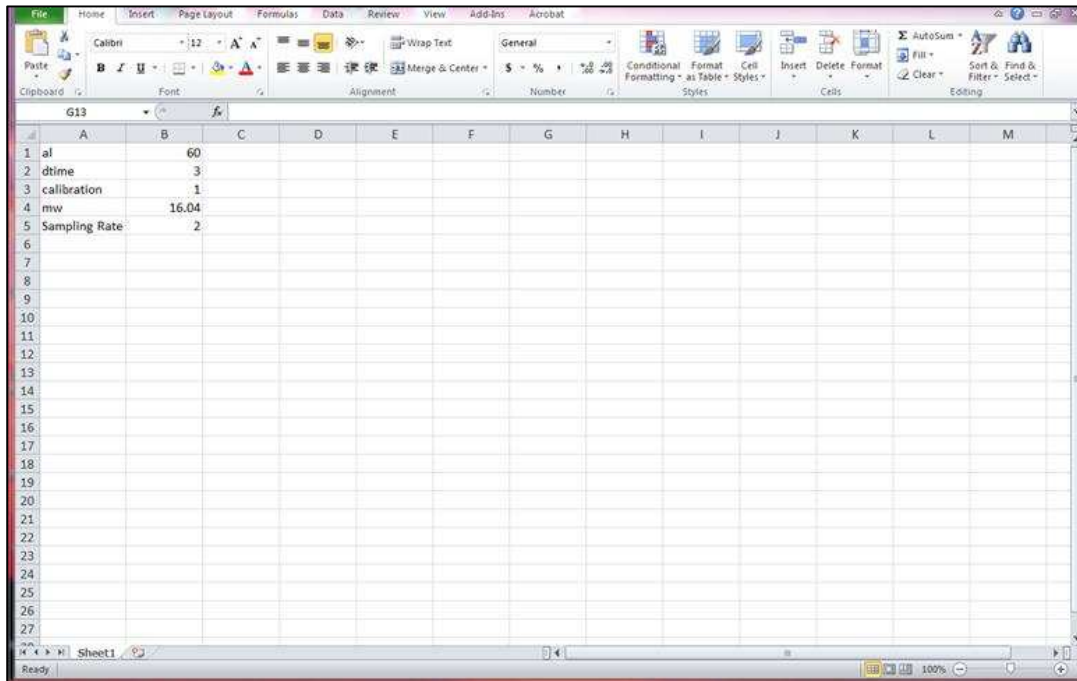

Figure 4. Screenshot of Parameter.xls User Input Spreadsheet

The first parameter, **al**, is the wind direction angle filter (in degrees). This parameter allows the user to filter data used in the emission calculation based on the prevailing wind direction during the time the data was collected. For example, a wind direction angle filter of 60° would direct the emissions calculation program to use data from time periods only when the prevailing wind direction was ± 60° from the compass heading of the source location, with respect to the location of the measurement vehicle. A wind direction angle filter of 180° would direct the program to use all data collected for the emissions calculation (e.g. no wind filter). In preparation for the preliminary run of the *PG_Analysis_Methane_CSV* program for a particular dataset, the **al** parameter should be set to 180°.

The next parameter, **dtime**, is the instrument delay time (in seconds), determined from the delay tests conducted during the measurement campaign, and described in Section 2.

The third parameter, **calibration**, is a calibration factor that can be used to correct concentration data, based on pre-deployment instrument calibration experiments. The default value for this parameter is 1, but this value may be adjusted depending on the results of the calibration experiments (e.g. if the results of the calibration

Page 14 of 64

experiments indicate the analyzer has a 20% bias in concentration measurements, the **_calibration_** value would be entered as 1.20).

The fourth parameter, **_mw_**, is the molecular weight of the target compound, in grams/mole. Because this document describes methane emissions calculations, this value is entered as 16.04.

The final parameter, **_Sampling Rate_**, is the data sampling rate, in Hz, used during the measurement campaign. The default value for this parameter is 2.

After all parameter values are entered into the spreadsheet, the file is saved in the "Analysisfiles" subfolder.

3.3 Running the _PG_Analysis_Methane_CSV_ Program for Emissions Calculations

The program is now ready to calculate emission rates from the surveys. Run the program by clicking on the "Debug" icon, and then click on "Run", as shown in Figure 5.

SOP for Analysis of US EPA GMAP-REQ-DA Method Data for Methane
Emission Rate Quantification using the Point Source Gaussian Method
SOP 601 for OTM 33A
September 2013 (Revision 0)
Page 15 of 64
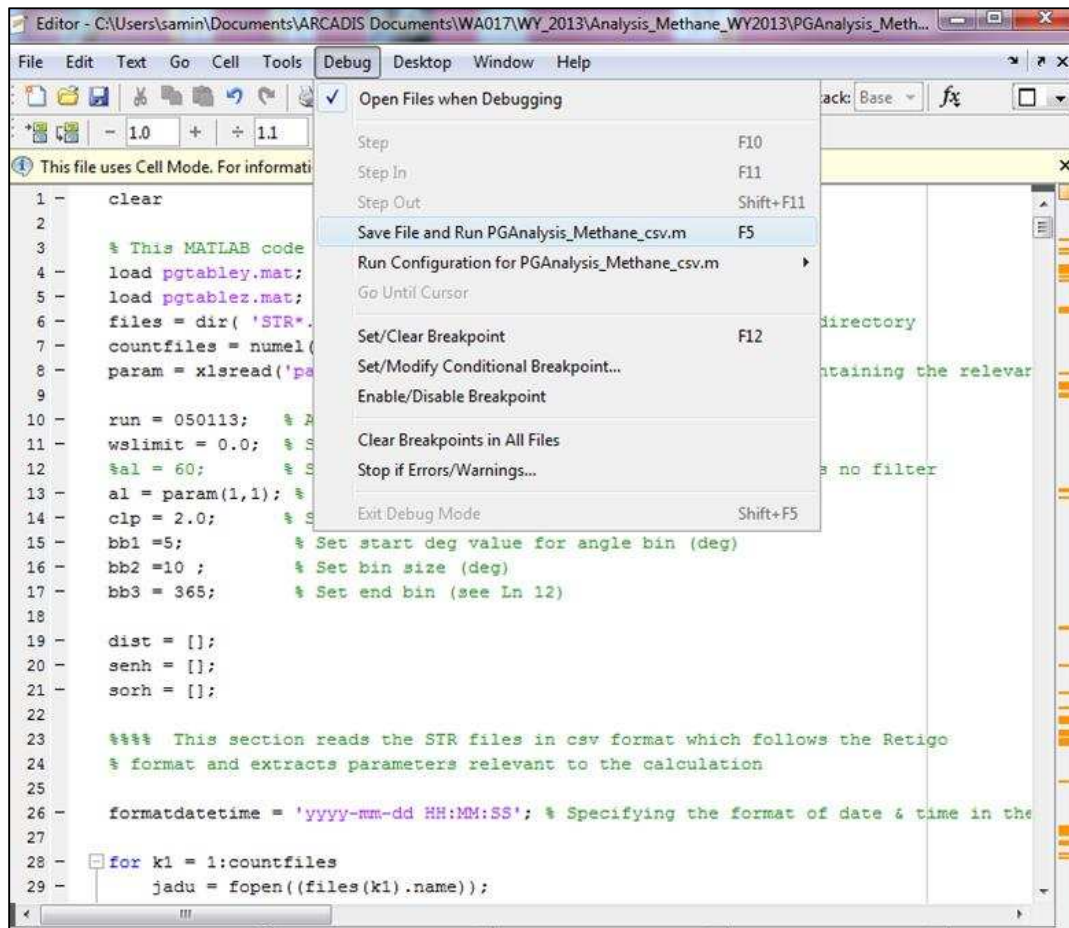

Figure 5. Screenshot from *PG_Analysis* program showing initiation of the program

When the emissions calculations are complete, the program will create a results output file, *Summary_Processed_Methane.xls*, in the "Analysisfiles" subfolder, which includes emission estimate results from all surveys conducted during a particular measurement campaign. An example results output file is shown in Appendix D of this document, including an explanation of all data fields.

In addition to the *Summary_Processed_Methane.xls* file, the program will create a "processed STR" file for each site survey from the measurement campaign. Data in the processed STR file have been time-aligned based on input from the *Parameter.xls* file. Note that the "Analysisfiles" subfolder from a particular measurement campaign will include one *Summary_Processed_Methane.xls* file, and multiple processed STR files (one for each site survey).

Next, open the *Summary_Processed_Methane.xls* file and inspect the values shown in columns **<u> and <w>**. All values in each of these columns should be close to "0", indicating that the orientation of the 3-D Sonic Anemometer instrument in the field was correct. After this has been confirmed, re-open and edit the *Parameter.xls* input file (described in Section 3.2) by changing the value of the **al** parameter to the default value of 60°. In the "Analysisfiles" subfolder, select and delete all "processed STR" files. Then, re-run *PG_Analysis_Methane_CSV* program using the procedure described at the beginning of this section. A new *Summary_Processed_Methane*.xls file will be created (overwriting the original file). This will be the final data output results file.

Note: The PG_Analysis_Methane_CSV analysis program is run utilizing a MatLab® platform, and the user must have MatLab® installed on their personal computer to use the program for emissions measurement calculations. The instructions presented in Sections 3.2 and 3.3 are applicable for using the PG_Analysis_Methane_CSV program in a MatLab® environment. However, an executable program, MethaneAnalysis.exe has been created for users who do not have MatLab® installed on their personal computer. The instructions for using the MethaneAnalysis.exe are identical to those presented in Sections 3.2 and 3.3, with the following exceptions:

1. The MethaneAnalysis.exe is installed on a personal computer in a folder called "Methane Analysis", under a subfolder called

Page 16 of 64

"distrib". After all converted .csv STR files have been created (using procedures detailed in Section 3.1), the converted files should be pasted into the "distrib" subfolder. The completed Parameter.xls user input spreadsheet should also be saved in the "distrib" subfolder.

2. *After the necessary files have been saved in the "distrib" subfolder, the MethaneAnalysis.exe program is run by simply double-clicking on the program icon. The results output file will be created in the "distrib" subfolder.*

4.0 Wind Rose/Concentration Plot Quality Assurance Program

The wind rose/concentration plot quality assurance program creates a plot that displays the measured methane concentrations from each site survey, plotted on a four-quadrant graph, as a function of prevailing wind direction during the measurements. The origin of the graph represents the location of the measurement vehicle during the survey. Methane concentration values are plotted using a color scale, with the highest methane concentrations shown in red and orange colors, the lowest concentrations shown in blue and green, and intermediate concentration values shown in yellow. Concentrations plotted in the northeast quadrant of the graph represent concentrations measured while winds were blowing from the northeast. Concentrations plotted in the southeast quadrant represent measurements with prevailing winds from the southeast, etc. The plot is created to verify the location of the source of emissions detected with the instrumentation (the approximate location of the emissions source is found by starting at the origin of the graph and following the axis of highest methane concentrations, which should terminate in the vicinity of the emissions source. The program also creates a wind direction histogram, showing the frequency of prevailing wind directions.

The plots are created using a custom-designed MatLab® based program called *WindCH4Source.m.* The *WindCH4Source.m* program code is presented in Appendix E of this document. The *WindCH4Source.m* is run using the following procedures:

1. Copy all "processed STR" files from the "Analysisfiles" subfolder (discussed in Section 3.3) into a new folder that also includes the *WindCH4Source.m* MATLAB® code.
2. The program can be executed using either absolute wind data from the AIO Compact Weather Station, or azimuthal wind direction data from the 3D Sonic Anemometer. The wind direction parameter is represented by the variable "**wddir**" in the program code, as shown in line 16 of Figure 6. No changes to the program code are necessary to utilize the AIO Compact Weather Station wind data to create the wind rose/concentration plots. However, in order to use the 3D Sonic Anemometer azimuthal wind direction data to change the plots, the program must be modified by deleting the "%" in line 15, and inserting "%" in line 16, before the variable "wddir".

The code is executed by clicking on the "Run" icon, and then clicking on "Run WindCH4Source" from the dropdown menu, as shown in Figure 6.

Page 18 of 64

Figure 6. Screenshot of *WindCH4Source.m* Program Code

The *WindCH4Source.m* program creates plots for each processed STR file (each site survey from a particular measurement campaign), a *CH4Source* file (shown in Figure 7), and a *WindHist* file (shown in Figure 8). The *CH4Source* file is used to confirm the location of the emissions source, with respect to the location of the measurement vehicle.

Heading Definitions

Filename: Study code and date of survey, denoted by SSMMDDYY where SS=study code, MM=month, DD=day, and YY=year.

Event: Event is the experiment number of the given day.

Distance (m): The distance from the measurement location to the methane emission source. This value is originally entered by the user in the field, and the MATLAB Analysis code pulls it from the STR file created.

Sensor Height (m): The height of the sensor. This value is entered by the user in the field. If no value is entered, the default value is zero.

Source Height (m): The height of the source, and often the user cannot measure it. In this case, the default value entered is zero.

A1 + bkgCH4: Peak methane value obtained from the Gaussian fit added to the background methane value

bkgCH4 (ppm): The background methane concentration which is calculated to be the mean of the lowest 5 % of the methane concentration values.

Pressure (mbar): The mean ambient pressure value measured in mbar.

<u>: The mean value of the velocity in the y direction

<v>: The mean value of the velocity in the x direction

<w>: The mean value of the velocity in the z direction

<t>: The mean temperature value in degrees Celsius

<u2>: The mean value of the dot product of u.u

<v2>: The mean value of the dot product of v.v

<w2>: The mean value of the product of w.w

<t2>: The mean value of the product of t.t, where t is measured temperature in degrees Celsius.

<uv>: The mean value of the dot product of u and v

<uw>: The mean value of the dot product of u and w

<ut>: The mean value of the dot product of u and t

<vw>: The mean value of the dot product of v and w

SOP for Analysis of US EPA GMAP-REQ-DA Method Data for Methane
Emission Rate Quantification using the Point Source Gaussian Method
SOP 601 for OTM 33A
September 2013 (Revision 0)
Page 56 of 64

<vt>: The mean value of the dot product of v and t

<wt>: The mean value of the dot product of w and t

GPS Latitude: The average GPS latitude of the location where the measurements were collected

GPS STDev Latitude: Computed standard deviation of the GPS Latitude values

GPS Longitude: The average GPS longitude of the location where the measurements were collected

GPS STDev Longitude: Computed standard deviation of the GPS Longitude values

Mean CO2 (ppm): The average carbon dioxide values measured in ppm

STDEV CO2: Computed standard deviation of the carbon dioxide values

5% of the Data: Number of data values in 5% of the data

Highest Methane: Highest methane concentration value recorded during the survey

Mean of the Highest 5% of Methane Conc (ppm): Average of the highest 5 % of the methane concentration values measured in ppm

STDev of the Highest 5% of Methane Conc: Standard deviation of the highest 5 % of methane concentration values

Lowest Methane: The lowest methane concentration value measured during the survey

Background Methane: The average of the lowest 5 % of methane concentration values

STDev of the Background Methane: Standard deviation of the lowest 5 % of methane concentration values

Mean Methane: The average of all the methane concentration values recorded, after the time alignment, during the survey

Mean Methane-bkg: Value obtained after subtracting the average methane concentration value from the computed background methane concentration value

3DS 3D Wind Speed: The computed wind speed performed in the MATLAB Analysis code using data from the 3D Sonic Anemometer

Temp.: The average ambient temperature value during the survey, in degrees Kelvin

Mean 2DWind: The average value of the absolute wind direction computed by the MATLAB code using data from the AIO Compact Weather Station

SOP for Analysis of US EPA GMAP-REQ-DA Method Data for Methane
Emission Rate Quantification using the Point Source Gaussian Method
SOP 601 for OTM 33A

Page 57 of 64

Mean 3DWind: The average value of the azimuthal rotated wind direction calculated by the MATLAB code using data from the3D Sonic Anemometer

Std WD 2D: Standard deviation of the absolute wind direction measured with the 3D Sonic Anemometer

Std WD 3D: Standard deviation of the azimuthal rotated wind direction measured with the 3D Sonic Anemometer

Turbulent Intensity: Ratio of the standard deviation of the wind speed in the z direction to the calculated mean wind speed

WS 2D PGI: Wind Stability Class based on the AIO Compact Weather Station Wind Speed value

WS 3D PGI: Wind Stability Class based on the 3D Wind Speed value

StdDev. WD 2D PGI: Wind Stability Class based on the standard deviation of the wind direction measured by the AIO Compact Weather Station

StdDev. WD 3D PGI: Wind Stability Class based on the standard deviation of the wind direction measured by the 3D Sonic Anemometer

Turbulent Intensity PGI: Wind Stability class based on the turbulent intensity

Weighted Avg. PGI: This is the average of the Wind Stability Class

Estimated PGI: Since the weighted average PGI may not be an integer, the MATLAB analysis code converts the weighted average PGI value to an integer

PGσy: Plume width in the y-direction in meters retrieved from wind stability class tables presented in Appendix A

PGσz: Plume height in the z-direction in meters retrieved from wind stability class tables presented in Appendix A

Centroid Dir: Centroid angle in degrees

Angle Bin Size: Size of angle bins for Gaussian fit (default value of 10 degrees)

Wind Speed Cut: Wind speed filter value designating that wind speed values must be above a certain value to be included in data analysis

Accept Angle Limit: Value chosen for wind direction filter (default value is 60 degrees)

Bin Density Cut: Value designating that every wind angle bin must have this percentage of data to be included in the data analysis

a1: Peak methane value retrieved from Gaussian fit of methane concentration values

Emission Rate Quantification using the Point Source Gaussian Method
SOP 601 for OTM 33A
September 2013 (Revision 0)
Page 58 of 64

σ: Plume width in the y-direction in degrees retrieved from Gaussian fit of methane concentration values

CH4 a1: a1 value converted to units of g/m^3

σy: Plume width in degrees converted into units of distance (meters)

rsq: R square value of the Gaussian fit of methane concentration data, indicating how well the fit matches the data points

CountQA: Maximum number of values in the bin

TempQA: Ratio of the mean temperature measured by the AIO Weather Station to the mean temperature measured by the 3D Sonic Anemometer

3Dtemp stdev QA: Standard deviation of the 3D Sonic Anemometer temperature in degrees Celsius

3Dtemp min QA: Minimum value of the 3D Sonic Anemometer temperature in degrees Celsius

3Dtemp max QA: Maximum value of the 3D Sonic Anemometer temperature in degrees Celsius

PSG Emission Estimate: Methane emission estimate in grams per second
